Searches this list or its range for the provided [element] using the binary search algorithm.
The list is expected to be sorted into ascending order according to the Comparable natural ordering of its elements,
otherwise the result is undefined.
If the list contains multiple elements equal to the specified [element], there is no guarantee which one will be found.
`null` value is considered to be less than any non-null value.

The sequence produces values until it encounters first `null` value.
If [seed] is `null`, an empty

public fun <T>
Sequence<T>.chunked(size:
Int): Sequence<List<T>> {
 return windowed(size, size, partialWindows = true)
}

```

Splits this sequence into several lists each not exceeding the given [size] and applies the given [transform] function to an each.

`@return` sequence of results of the [transform] applied to an each list.

Note that the list passed to the [transform] function is ephemeral and is valid only inside that function.

You should not store it or allow it to escape in some way, unless you made a snapshot of it.

The last list may have less elements than the given [size].

`@param` size the number of elements to take in each list, must be positive and can be greater than the number of elements in this sequence.

The operation is `_intermediate_` and `_stateful_`.

`@sample`  
`samples.text.Strings.chunkedTransform`

Sequence<T>.chunked(size: Int, transform: (List<T>) -> R): Sequence<R> {

Returns a sequence containing all elements of the original sequence without the first occurrence of the given [element].

The operation is `_intermediate_` and `_stateless_`.

`minus(elements: Array<out T>): Sequence<T>` Returns a sequence containing all elements of original sequence except the elements contained in the given [elements] array. Note that the source sequence and the array being subtracted are iterated only when an `iterator` is requested from the resulting sequence. Changing any of them between successive calls to `iterator` may affect the result. The [elements] array may be converted to a [HashSet] to speed up the operation, thus the elements are required to have a correct and stable implementation of `hashCode()` that doesn't change between successive invocations. `Sequence<T>.zipWithNext(): Sequence<Pair<T, T>> {`

 * For non-Kotlin types, it means the type or the symbol which was declared with this type is annotated with a runtime-retained nullability annotation such as [javax.annotation.Nullable].
 * Note that even if [isMarkedNullable] is false, values of the type can still be `null`.
 * This may happen if it is a type of the type parameter with a nullable upper bound:

/**
 * Gives a declaration (a function, a property or a class) specific name in JavaScript.
 * This may be useful in the following cases:
 * - There are two functions for which the compiler gives same name in JavaScript, you can mark one with `@JsName(...)` to prevent the compiler from reporting error.
 * - You are writing a JavaScript library in Kotlin. The compiler produces mangled names for functions with parameters, which is unnatural for usual JavaScript developer. You can put `@JsName(...)` on functions you want to be available from JavaScript.
 * - For some reason you want to rename declaration, e.g. there's common term in JavaScript for a concept provided by the declaration, which is uncommon in Kotlin.
 * Example:
 * ```kotlin
 * class Person(val name: String) {
 * fun hello() {
 * println("Hello $name!")
 * }
 * }
 * ```
 */

```

```

@JsName("helloWithGreeting") fun hello(greeting: String) {
 println("$greeting $name!")
}

```

It's required to denote a valid JavaScript identifier.

```

@Retention(AnnotationRetention.BINARY)
@Target(CLASS, FUNCTION, PROPERTY, CONSTRUCTOR, PROPERTY_GETTER, PROPERTY_SETTER)
public actual annotation class JsName(actual val name: String)

```

Denotes an `external` declaration that must be imported from native JavaScript library.

The compiler produces the code relevant for the target module system, for example, in case of CommonJS, it will import the declaration via the `require(...)` function.

The annotation can be used on top-level external declarations (classes, properties, functions) and files.

In case of file (which can't be `external`) the following rule applies: all the declarations in the file must be `external`. By applying `@JsModule(...)` on a file you tell the compiler to import a JavaScript object that contain all the declarations from the file.

Example:

```

kotlin
@JsModule("jquery") external abstract class JQuery() {
 // some declarations here
}
@JsModule("jquery") external fun JQuery(element: Element): JQuery

```

external import name of a module to import declaration from.

It is not interpreted by the Kotlin compiler, it's passed as is directly to the target module system.

```

@see JsNonModule
@Retention(AnnotationRetention.BINARY)
@Target(CLASS, PROPERTY, FUNCTION, FILE)
public annotation class JsModule(val import: String)

```

Denotes an `external` declaration that can be used without module system.

By default, an `external` declaration is available regardless your target module system.

However, by applying [JsModule] annotation you can make a declaration unavailable to plain module system.

Some JavaScript libraries are distributed both as a standalone downloadable piece of JavaScript and as a module available as an npm package.

To tell the Kotlin compiler to accept both cases, you can augment [JsModule] with the `@JsNonModule` annotation.

For example:

```

kotlin
@JsModule("jquery")
@JsNonModule
@JsName("$") external abstract class JQuery() {
 // some declarations here
}
@JsModule("jquery")
@JsNonModule
@JsName("$") external fun JQuery(element: Element): JQuery

```

see JsModule

```

@Retention(AnnotationRetention.BINARY)
@Target(CLASS, PROPERTY, FUNCTION, FILE)
public annotation class JsNonModule

```

Adds prefix to `external` declarations in a source file.

JavaScript does not have concept of packages (namespaces). They are usually emulated by nested objects.

The compiler turns references to `external` declarations either to plain unprefix names (in case of plain modules) or to plain imports.

However, if a JavaScript library provides its declarations in packages, you won't be satisfied with this.

You can tell the compiler to generate additional prefix before references to `external` declarations using the `@JsQualifier(...)` annotation.

Note that a file marked with the `@JsQualifier(...)` annotation can't contain non-`external` declarations.

Example:

```

@file:JsQualifier("my.jsPackageName") package some.kotlinPackage
external fun foo(x: Int)
external fun bar(): String

```

property value the qualifier to add to the declarations in the generated code.

It must be a sequence of valid JavaScript identifiers separated by the `.` character.

Examples of valid qualifiers are: `foo`, `bar.Baz`, `\_.\$.f`.

```

@see JsModule
@Retention(AnnotationRetention.BINARY)
@Target(AnnotationTarget.FILE)
public annotation class JsQualifier(val value: String)

```

Marks experimental JS export annotations.

Note that behaviour of these annotations will likely be changed in the future.

Usages of such annotations will be reported as warnings unless an explicit opt-in with the [OptIn] annotation, e.g. `@OptIn(ExperimentalJsExport::class)`, or with the `-Xopt-in=kotlin.js.ExperimentalJsExport` compiler option is given.
