Introduction

This document describes the how to configure and troubleshoot the Cisco Meeting Server (CMS) Web App implementation of Single Sign On (SSO).

Prerequisites

Requirements

Cisco recommends you have knowledge of these topics:

- CMS Callbridge version 3.1 or later
- CMS Webbridge version 3.1 or later
- Active Directory Server
- Identify Provider (IdP)

Components Used

The information in this document is based on these software and hardware versions:

- CMS Callbridge version 3.2
- CMS Webbridge version 3.2
- Microsoft Active Directory Windows Server 2012 R2
- Microsoft ADFS 3.0 Windows Server 2012 R2

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

Background

CMS 3.1 and later introduced the capability for users to sign in using an SSO without the need to enter their password every time the user logs in, because a single session is created with the Identify provider. This feature is using the Security Assertion Markup Language (SAML) version 2.0 as the SSO Mechanism.

 **Note:** CMS only supports HTTP-POST bindings in the SAML 2.0 and rejects any Identify Provider with no HTTP-POST bindings available.

 **Note:** When SSO is enabled, basic LDAP authentication is no longer possible.

Configure

Network Diagram

ADFS Installation and Initial setup

This deployment scenario uses Microsoft Active Directory Federation Services (ADFS) as the Identity Provider (IdP) and therefore, it is suggested to have an ADFS (or intended IdP) installed and running prior to this configuration.

Map CMS Users to Identity Provider (IdP)

In order to have users get valid authentication, they must to be mapped in the Application Programming Interface (API) for a correlating field provided by IdP. The option used for this is the **authenticationIdMapping** in the **ldapMapping** of the API.

1. Navigate to **Configuration > API** on the CMS Web Admin GUI

Co

2. Locate existing (or creating a new) LDAP Mapping under **api/v1/ldapMappings/<GUID-of-Ldap-Mapping>**.

API objects

This page shows a list of the objects supported by the API. Where you see a ► control, you can expand that section to either see details of one specific section of configuration.

Filter (2 of 129 nodes)

[/api/v1/ldapMappings](#) ◀

◀ start < prev 1 - 2 (of 2) next >

object id	iidMapping
458ad270-860b-4bac-9497-b74278ed2086	\$sAMAccountName\$@brhuff.com

3. In the **ldapMapping** object selected, update the **authenticationIdMapping** to the LDAP attribute that is passed from the IdP. In the example, the option **\$sAMAccountName** is used as the LDAP attribute for mapping.

[/api/v1/ldapMappings/458ad270-860b-4bac-9497-b74278ed2086](#)

jidMapping	<input type="checkbox"/>	<input type="text" value="\$sAMAccountName\$@brhuff.com"/>	- present
nameMapping	<input type="checkbox"/>	<input type="text" value="\$cn\$"/>	- present
cdrTagMapping	<input type="checkbox"/>	<input type="text"/>	
coSpaceUriMapping	<input type="checkbox"/>	<input type="text" value="\$sAMAccountName\$.space"/>	- present
coSpaceSecondaryUriMapping	<input type="checkbox"/>	<input type="text"/>	
coSpaceNameMapping	<input type="checkbox"/>	<input type="text" value="\$cn's Space"/>	- present
coSpaceCallIdMapping	<input type="checkbox"/>	<input type="text"/>	
authenticationIdMapping	<input type="checkbox"/>	<input type="text" value="\$sAMAccountName\$"/>	- present

 **Note:** The **authenticationIdMapping** is used by the callbridge/database to validate the claim sent from the IdP in the SAMLResponse and provide the user with a JSON Web Token (JWT).

4. Perform an **LDAP sync** on the **ldapSource** associated with the recently modified **ldapMapping**:

For Example:

[/api/v1/ldapSyncs](#)

tenant	<input type="checkbox"/>	<input type="text"/>	<input type="button" value="Choose"/>
ldapSource	<input checked="" type="checkbox"/>	<input type="text" value="0b8de8cd-ccce-4ccb-89a8-08ba69e98ec7"/>	<input type="button" value="Choose"/>
removeWhenFinished	<input type="checkbox"/>	<unset>	

5. After the LDAP sync is completed, navigate in the CMS API in **Configuration > api/v1/users** and select a user that was imported and verify the **authenticationId** is populated correctly.

Object configuration	
userId	jdoe@brhuff.com
name	John Doe
email	john.doe@brhuff.com
authenticationId	jdoe
userProfile	d5cd50e4-e423-4ba6-bd17-7492b9ba5eb3

jdoe = sAMAccountName

Create Webbridge Metadata XML for IdP

The Microsoft ADFS allows a Metadata XML file to be imported as a Relying Trust Party to identify the Service Provider being used. There are a few ways to create the Metadata XML file for this purpose, however, there are a few attributes that must be present in the file:

Example of Webbridge Metadata with required values:

```
<?xml version="1.0"?>
- <md:EntityDescriptor entityID="https://meet.brhuff.local:443" ID="https://meet.brhuff.local:443"
xmlns:md="urn:oasis:names:tc:SAML:2.0:metadata">
- <md:SPSSODescriptor protocolSupportEnumeration="urn:oasis:names:tc:SAML:2.0:protocol" WantAssertionsSigned="true"
AuthnRequestsSigned="false">
<md:NameIDFormat>urn:oasis:names:tc:SAML:2.0:nameid-format:transient</md:NameIDFormat>
<md:AssertionConsumerService index="0" Location="https://meet.brhuff.local:443/api/auth/sso/idpResponse"
Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"/>
</md:SPSSODescriptor>
</md:EntityDescriptor>
```

1. **entityID** - This is the Webbridge3 server address (FQDN/Hostname) and associated port that is reachable by browsers for users.

Note: If there are multiple Webbridges using a single URL, this must be a load balancing address.

2. **Location** - This is the location in which the HTTP-POST AssertionConsumerService for the Webbridge Address. This is what tells the IdP where to redirect an authenticated user after sign-in. This must be set to the idpResponse URL:
<https://<WebbridgeFQDN>:<port>/api/auth/sso/idpResponse>. For example, <https://join.example.com:443/api/auth/sso/idpResponse>.
3. **OPTIONAL - Public Key for Signing** - this is the public key (certificate) for signing, which is be used by the IdP to verify AuthRequest from Webbridge. This **MUST** match with the private key 'sso_sign.key' on the SSO bundle uploaded on Webbridge so that the IdP can use the public key (certificate) to verify the signature. You can use an existing certificate from your deployment. Open the certificate in a text file and copy the content into the Webbridge Metadata file. Use the matching key for the certificate used in your sso_xxxx.zip file as the sso_sign.key file.
4. **OPTIONAL - Public Key for Encryption** - this is the public key (certificate) that the IdP is use to encrypt SAML information sent back to Webbridge. This **MUST** match the private key 'sso_encrypt.key' on the SSO bundle uploaded on Webbridge, so that Webbridge can decrypt what is sent back by IdP. You can use an existing certificate from your deployment. Open the certificate in a

text file and copy the content into the Webbridge Metadata file. Use the matching key for the certificate used in your sso_XXXX.zip file as the sso_encrypt.key file.

Example of Webbridge Metadata to be imported into IdP with optional public key (certificate) data:

```
<?xml version="1.0"?>
- <md:EntityDescriptor entityID="https://meet.brhuff.local:443" ID="https://meet.brhuff.local:443" xmlns:md="urn:oasis:names:tc:SAML:2.0:metadata">
- <md:SPSSODescriptor protocolSupportEnumeration="urn:oasis:names:tc:SAML:2.0:protocol" WantAssertionsSigned="true" AuthnRequestsSigned="true">
- <md:KeyDescriptor use="signing">
- <ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
- <ds:X509Data>
- <ds:X509Certificate>MIIFwTCCBmqAwIBAgIT...
- </ds:X509Certificate>
- </ds:X509Data>
- </ds:KeyInfo>
- </md:KeyDescriptor>
- <md:KeyDescriptor use="encryption">
- <ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
- <ds:X509Data>
- <ds:X509Certificate>MIIFwTCCBmqAwIBAgIT...
- </ds:X509Certificate>
- </ds:X509Data>
- </ds:KeyInfo>
- </md:KeyDescriptor>
- <md:NameIDFormat urn:oasis:names:tc:SAML:2.0:nameid-format:transient />
- <md:AssertionConsumerService index="0" Location="https://meet.brhuff.local:443/api/auth/sso/idpResponse" Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"/>
- </md:SPSSODescriptor>
</md:EntityDescriptor>
```

Import Metadata for Webbridge into Identity Provider (IdP)

Once the Metadata XML has been created with the proper attributes the file can be imported into the Microsoft ADFS server to create a Relying Trust Party.

1. Remote Desktop into the Windows Server hosting the ADFS services
2. Open the AD FS Management Console, which can usually be accessed through the Server Manager.

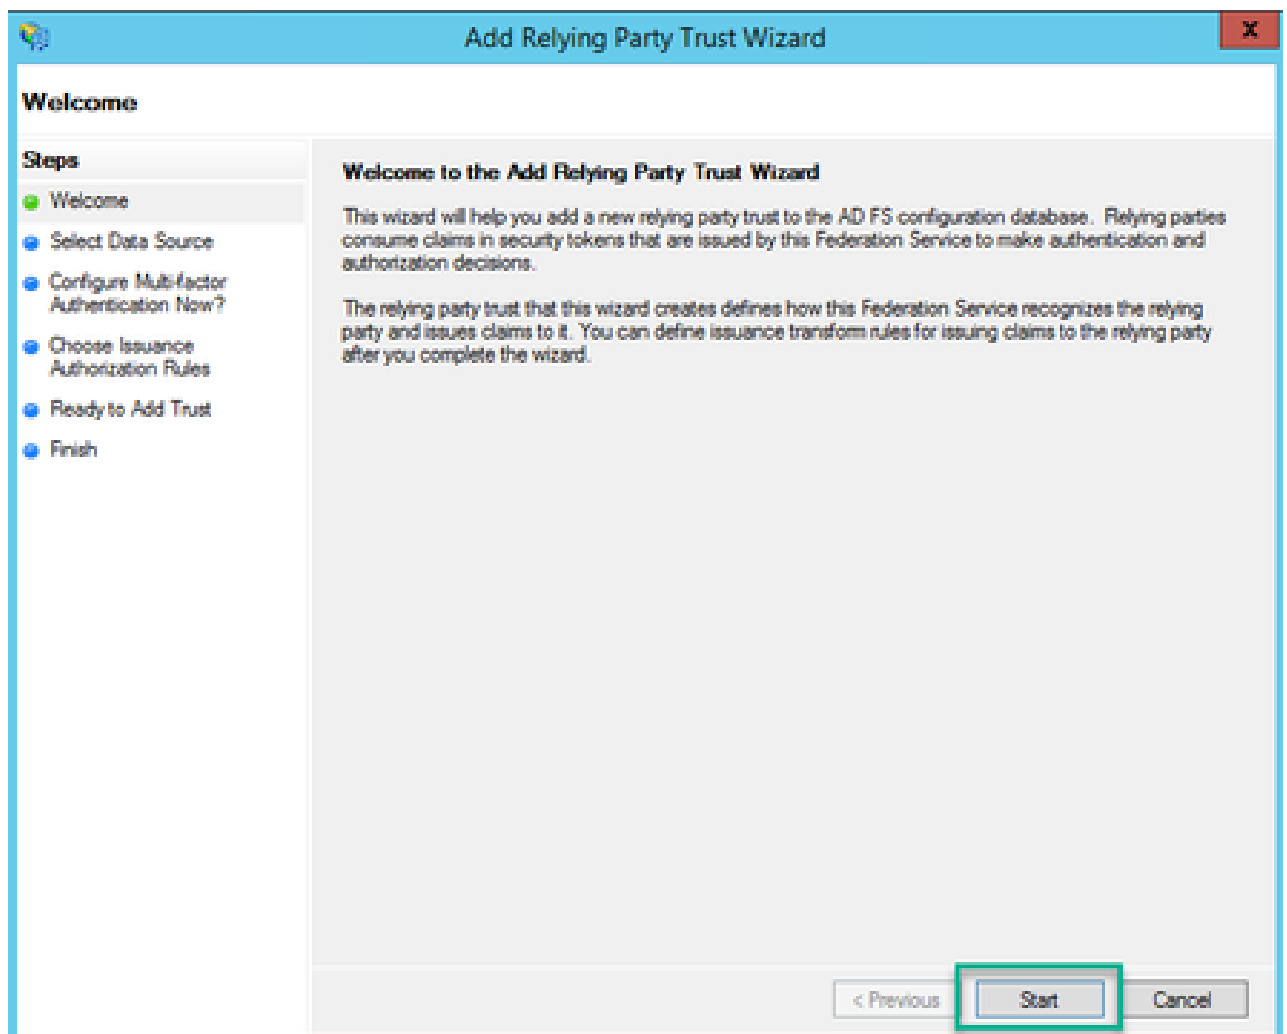

3. Once in the ADFS Management console, navigate to **ADFS > Trust Relationships > Relying Party Trust** in the Left pane.

4. In the Right pane of the ADFS Management Console, select the **Add Relying Party Trust...** option.

5. After making this select, the **Add Relying Party Trust Wizard** opens. Select the **Start** option.

6. On the **Select Data Source** page, select the radio button for **Import data about the relying party from a file** and select **Browse** and navigate to the location of the Webbridge MetaData file.

7. On the **Specify Display Name** page, put a name to be displayed for the entity in ADFS (the Display Name does not server purpose for the ADFS communication and is purely informational).

8. On the **Configure Multi-factor Authentication Now?** page, leave as default and select **Next**.

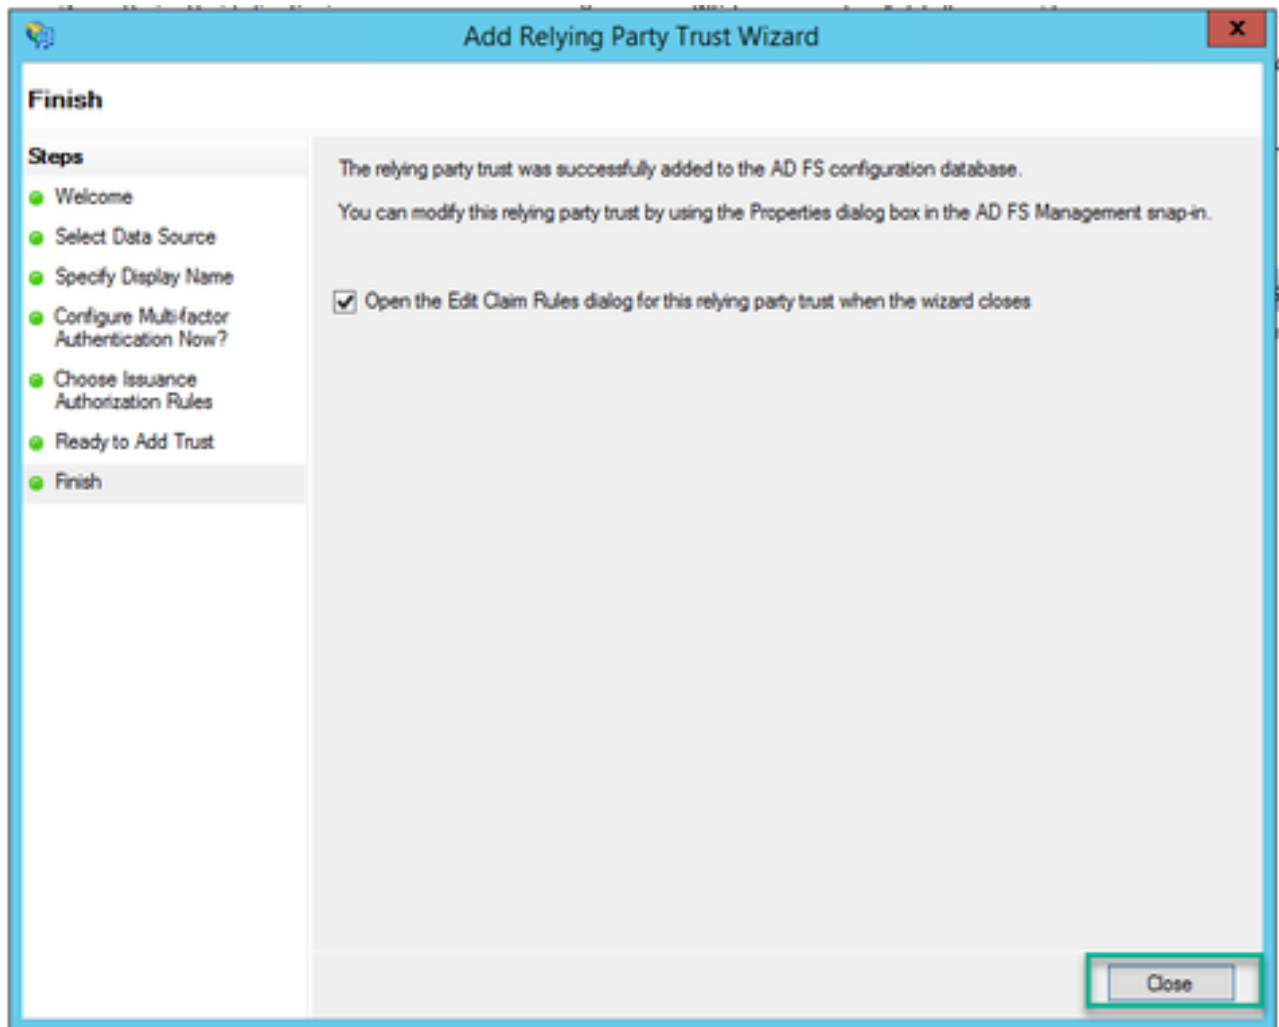

9. On the **Choose Issuance Authorization Rules** page, leave as selected for **Permit all users to access this relying party**.

10. On the **Ready to Add Trust** page, the imported details of the Relying Trust Party for Webbridge can be reviewed through the tabs. Check the **Identifiers** and **Endpoints** for the URL details for Webbridge Service Provider.

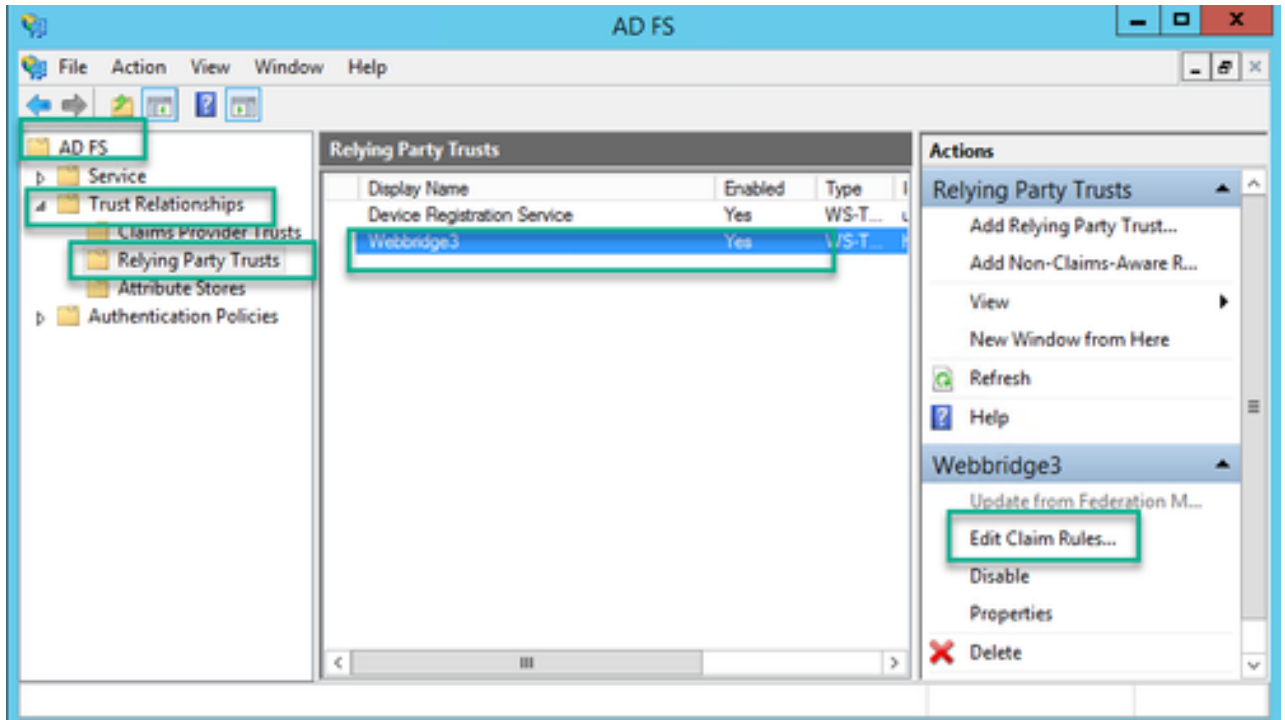

11. On the **Finish** page, select **Close** option to close the wizard and continue with editing claim rules.

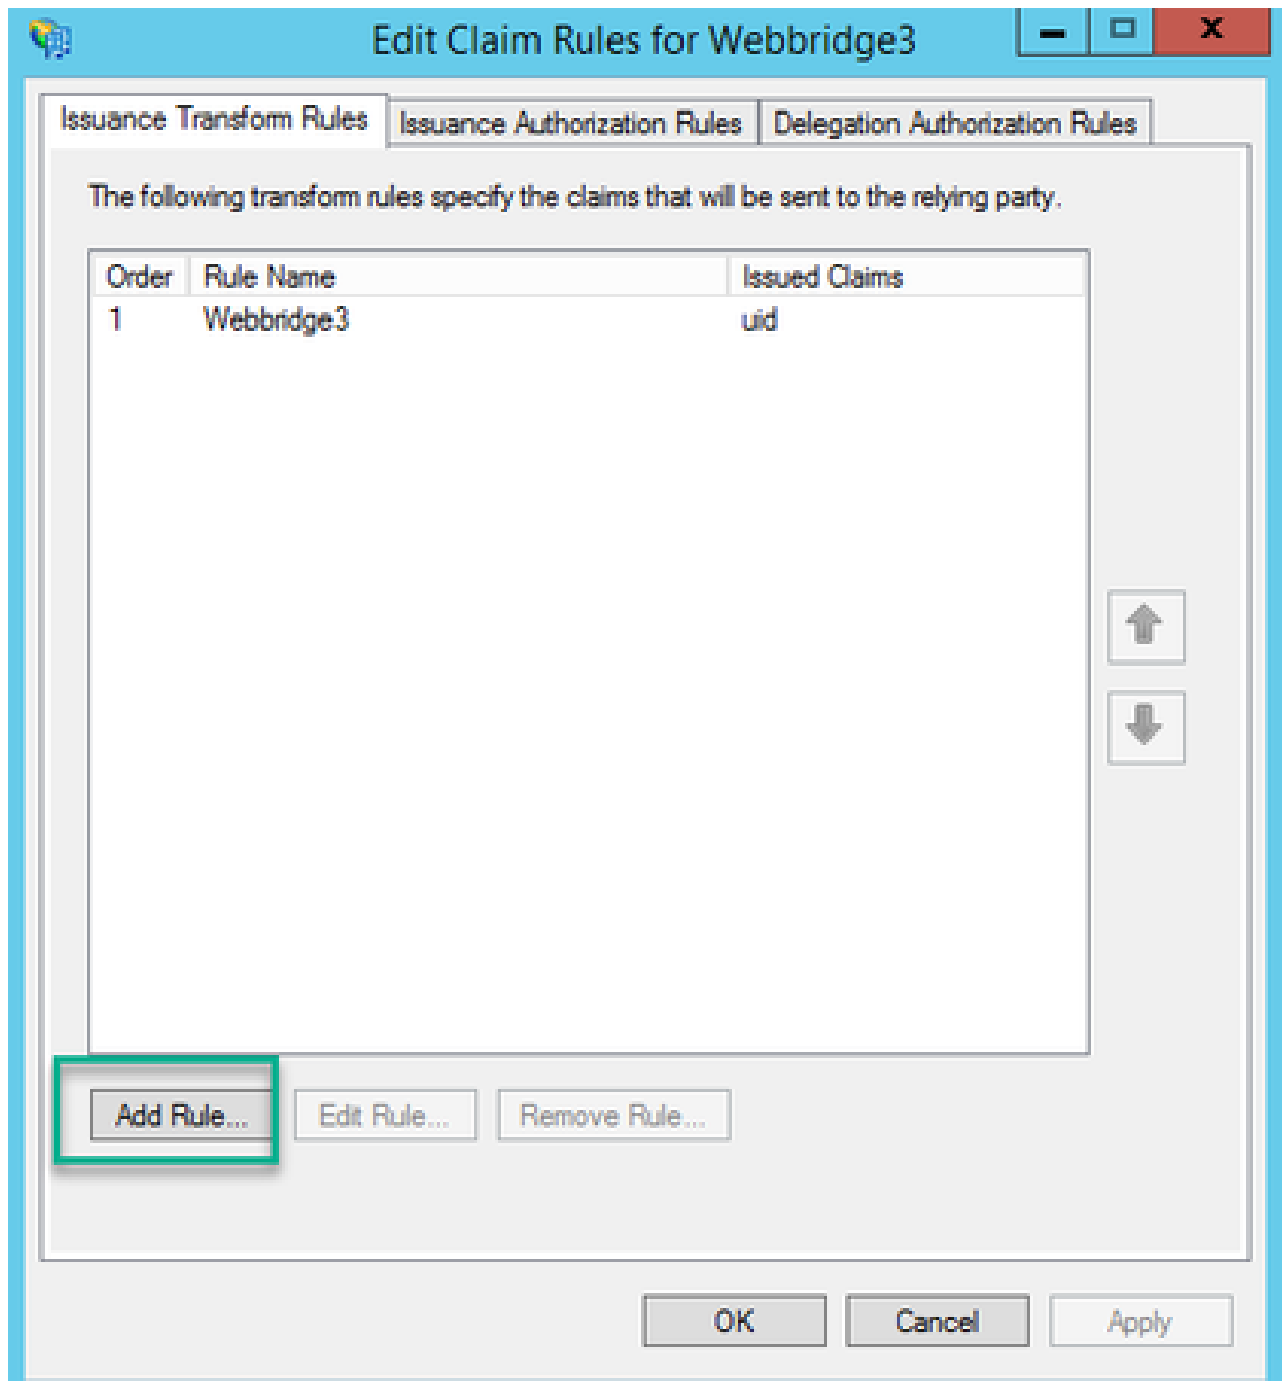

Create Claim Rules for the Webbridge Service on the IdP

Now that the Relying Party Trust has been created for the Webbridge, claim rules can be created to match specific LDAP Attributes to outgoing claim types to be provided to the Webbridge in the SAML Response.

1. In the **ADFS Management console**, highlight the **Relying Party Trust** for the Webbridge and select **Edit Claim Rules** on the right pane.

2. On the **Edit Claim Rules** for <DisplayName> page, select the **Add Rule...**

3. On the **Add Transform Claim Rule Wizard** page, select **Send LDAP Attributes as Claims** for the Claim rule template option and select **Next**.

4. On the **Configure Claim Rule** page, configure the claim rule for the **Relying Party Trust** with these values:

1. **Claim rule name** = this must be a name given to the rule in ADFS (for rule reference only)
2. **Attribute store** = Active Directory
3. **LDAP Attribute** = This must match the **authenticationIdMapping** in the Callbridge API. (For example, \$sAMAccountName\$.)
4. **Outgoing Claim Type** = This must match the **authenticationIdMapping** in the Webbridge SSO **config.json**. (For example, uid.)

You can configure this rule to send the values of LDAP attributes as claims. Select an attribute store from which to extract LDAP attributes. Specify how the attributes will map to the outgoing claim types that will be issued from the rule.

Claim rule name:

Rule template: Send LDAP Attributes as Claims

Attribute store:

Mapping of LDAP attributes to outgoing claim types:

	LDAP Attribute (Select or type to add more)	Outgoing Claim Type (Select or type to add more)
▶	<input type="text" value="SAM-Account-Name"/>	<input type="text" value="uid"/>
⊞	<input type="text"/>	<input type="text"/>

Create SSO Archive ZIP file for Webbridge:

This configuration is what the Webbridge references to validate the SSO configuration for supported domains, authentication mapping, and so on. These rules must be considered for this part of the configuration:

- The ZIP file MUST start with **sso_** prefixed to the file name (for example, **sso_cmstest.zip**).
- Once this file is uploaded, Webbridge disables basic authentication and ONLY SSO can be used for the Webbridge this has been uploaded to.
- If there are multiple Identity Providers used, a separate ZIP file must be uploaded with a different naming schema (STILL prefixed with the **sso_**).
- When creating the zip file, be sure to highlight and zip the file contents and do not put the required files into a folder and zip that folder.

The contents of the zip file are made up of 2 to 4 files, depending if encryption is being used or not.

Filename	Description	Required?
idp_config.xml	This is the MetaData file that can be collected by the idP. In ADFS this can be located by going to <a href="https://<ADFSFQDN>/FederationMetadata/2007-06/FederationMetadata.xml">https://<ADFSFQDN>/FederationMetadata/2007-06/FederationMetadata.xml .	YES
config.json	This is the JSON file in which Webbridge uses to validate the supported domains, authentication mapping for SSO.	YES
sso_sign.key	This is the private key for public signing key configured on the Identify Provider. Only needed for securing the signed data	NO
sso_encrypt.key	This is the private key for public encrypting key configured on the Identify Provider. Only needed for securing the encrypted data	NO

Obtain and configure the idp_config.xml

1. On the ADFS server (or a location that has access to the ADFS), open a Web Browser.
2. In the Web Browser, enter URL: <https://<ADFSFQDN>/FederationMetadata/2007-06/FederationMetadata.xml> (You can also use localhost instead of the FQDN if you are locally on the ADFS server). This downloads the file **FederationMetadata.xml**.

3. Copy downloaded file to a location where the zip file is being created and rename to **idp_config.xml**.

Name

config.json

FederationMetadata.xml

Properties

Local Disk (D:) > brentssoconfig > SSOconfig

Create the config.json File with Contents

The **config.json** contains the these 3 attributes and they must be contained within brackets, { }:

1. **supportedDomains** - This is a list of domains that are checked for SSO authentication against the IdP. Multiple domains can be separated by a comma.
2. **authenticationIdMapping** - This is the parameter that is passed back as a part of the outgoing claim rule from the ADFS/IdP. This must match the name value of the outgoing claim type on the IdP. Claim Rule.
3. **ssoServiceProviderAddress** - This is the FQDN URL to which the Identify Provider sends the SAML responses to. This must be the Webbridge FQDN.

The diagram illustrates the configuration flow for SSO authentication. It consists of three main components:

- config.json:** A text editor showing the following JSON content:

```
1 {  
2   "authenticationIdMapping": "uid",  
3   "ssoServiceProviderAddress": "https://meet.brhuff.local:443",  
4   "supportedDomains": ["brhuff.com"]  
5 }
```

 - An annotation points to the 'supportedDomains' array: "supported domain of 'brhuff.com' for SSO authentication".
 - An annotation points to the 'ssoServiceProviderAddress' value: "the URL of Webbridge for IdP to send response to".
- ADFS Claim Rule:** A screenshot of the ADFS management console showing a claim rule named 'Webbridge'.
 - The rule template is 'Send LDAP Attributes as Claims'.
 - The attribute store is 'Active Directory'.
 - The LDAP attribute is 'SAM-Account-Name'.
 - The outgoing claim type is 'uid'.
 - An annotation points to the 'uid' claim type: "Configured as 'uid' to match outgoing claim on ADFS".
- CMS API Mapping:** A screenshot of the CMS API configuration page for the endpoint '/api/v1/ldapMappings/458ad270-860b-4bac-9497-b74278ed2086'.
 - The 'authenticationIdMapping' checkbox is checked, and its value is set to '\$SAMAccountName\$'.
 - An annotation points to this configuration: "Make sure the LDAP attribute used in ADFS for the Claim rule matches the authenticationIdMapping in the CMS API".

Set the sso_sign.key (OPTIONAL)

This file must contain the private key of the certificate used for signing in the Webbridge metadata that was imported to the IdP. The certificate used for signing can be set during import of the Webbridge metadata in the ADFS by populating the **X509Certificate** with the certificate information under the **<KeyDescriptor use=signing>** section. It can also be viewed (and imported) on ADFS in the **Webbridge Relying Trust Party** under **Properties > Signature**.

In the next example, you can see the callbridge certificate (CN=cmscb3.brhuff.local), which was added to the Webbridge metadata prior to being imported into ADFS. The private key inserted into the **sso_sign.key** is the one that matches the **cmscb3.brhuff.local** certificate.

This is an optional configuration and only needed if intending to encrypt the SAML Responses.

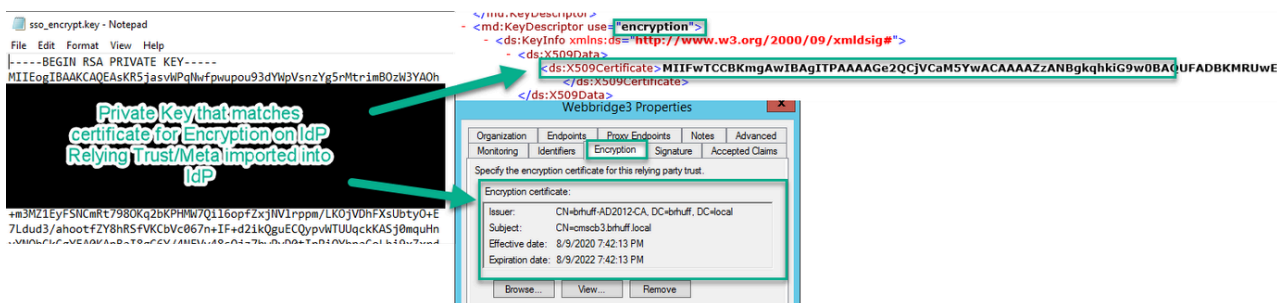

Set the sso_encrypt.key (OPTIONAL)

This file must contain the private key of the certificate used for encryption in the webbridge metadata that was imported to the IdP. The certificate used for encryption can be set during import of the Webbridge metadata in the ADFS by populating the **X509Certificate** with the certificate information under the **<KeyDescriptor use=encryption>** section. It can also be viewed (and imported) on ADFS in the **Webbridge Relying Trust Party** under **Properties > Encryption**.

In the next example, you can see the callbridge certificate (CN=cmscb3.brhuff.local), which was added to the Webbridge metadata prior to being imported into ADFS. The private key inserted into the 'sso_encrypt.key' is the one that matches the **cmscb3.brhuff.local** certificate.

This is an optional configuration and it is only needed if you intend to encrypt the SAML Responses.

Creating the SSO ZIP file

1. Highlight all the files intended to be used for the SSO config file.

Name

config.json

idp_config.xml

sso_encrypt.key

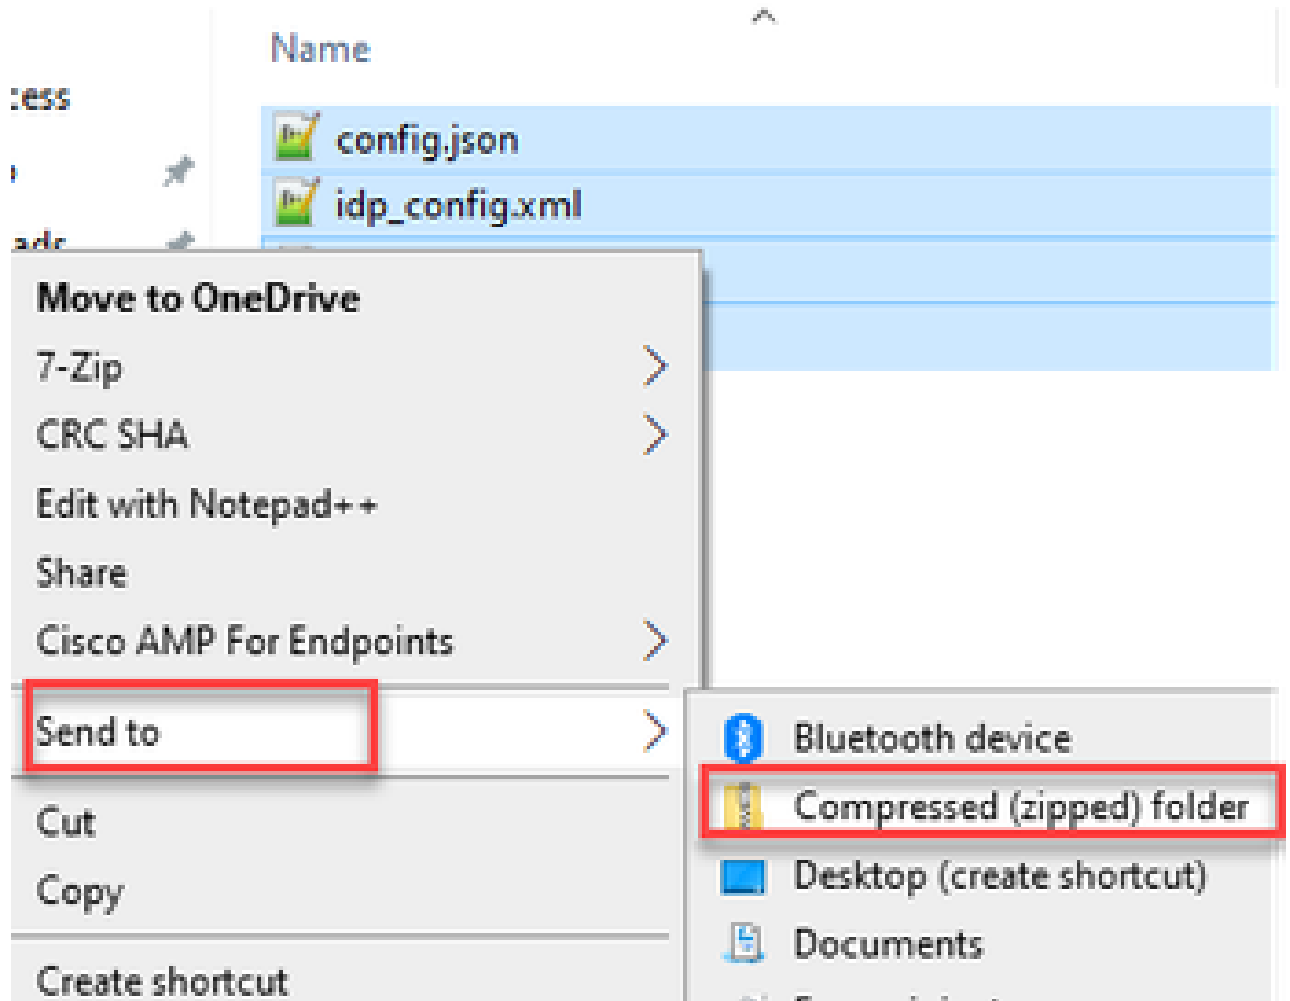

sso_sign.key

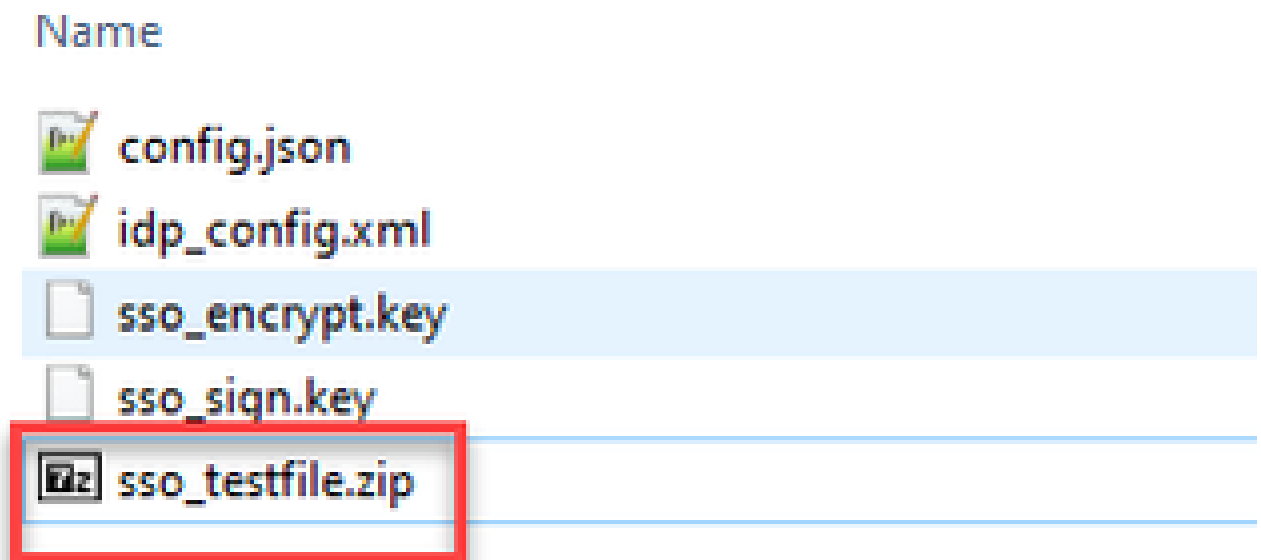

Caution: Do not zip the folder containing the files because this results in the SSO not working.

2. Right click on the highlight files and select **Send to > Compressed (zipped) folder.**

3. After the files have been zipped, rename them to the desired name with the `sso_` prefix:

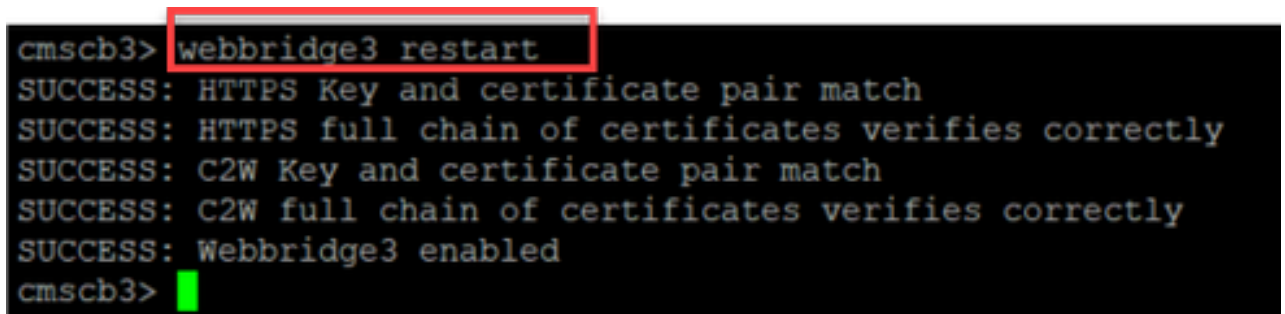

Upload the SSO Zip file(s) to Webbridge

Open an SFTP/SCP client, in this example WinSCP is being used, and connect to the server hosting Webbridge3.

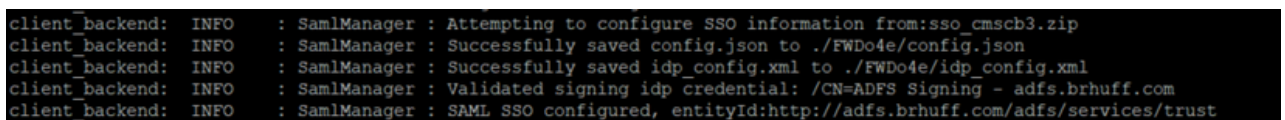

1. In the left pane, navigate to the location in which the SSO Zip file resides and either right click select upload or drag and drop the file.

2. Once the file has been uploaded completely to the Webbridge3 server, open an SSH session and run the command **webbridge3 restart**.

3. In the syslog, these messages indicate the SSO enable was successful:

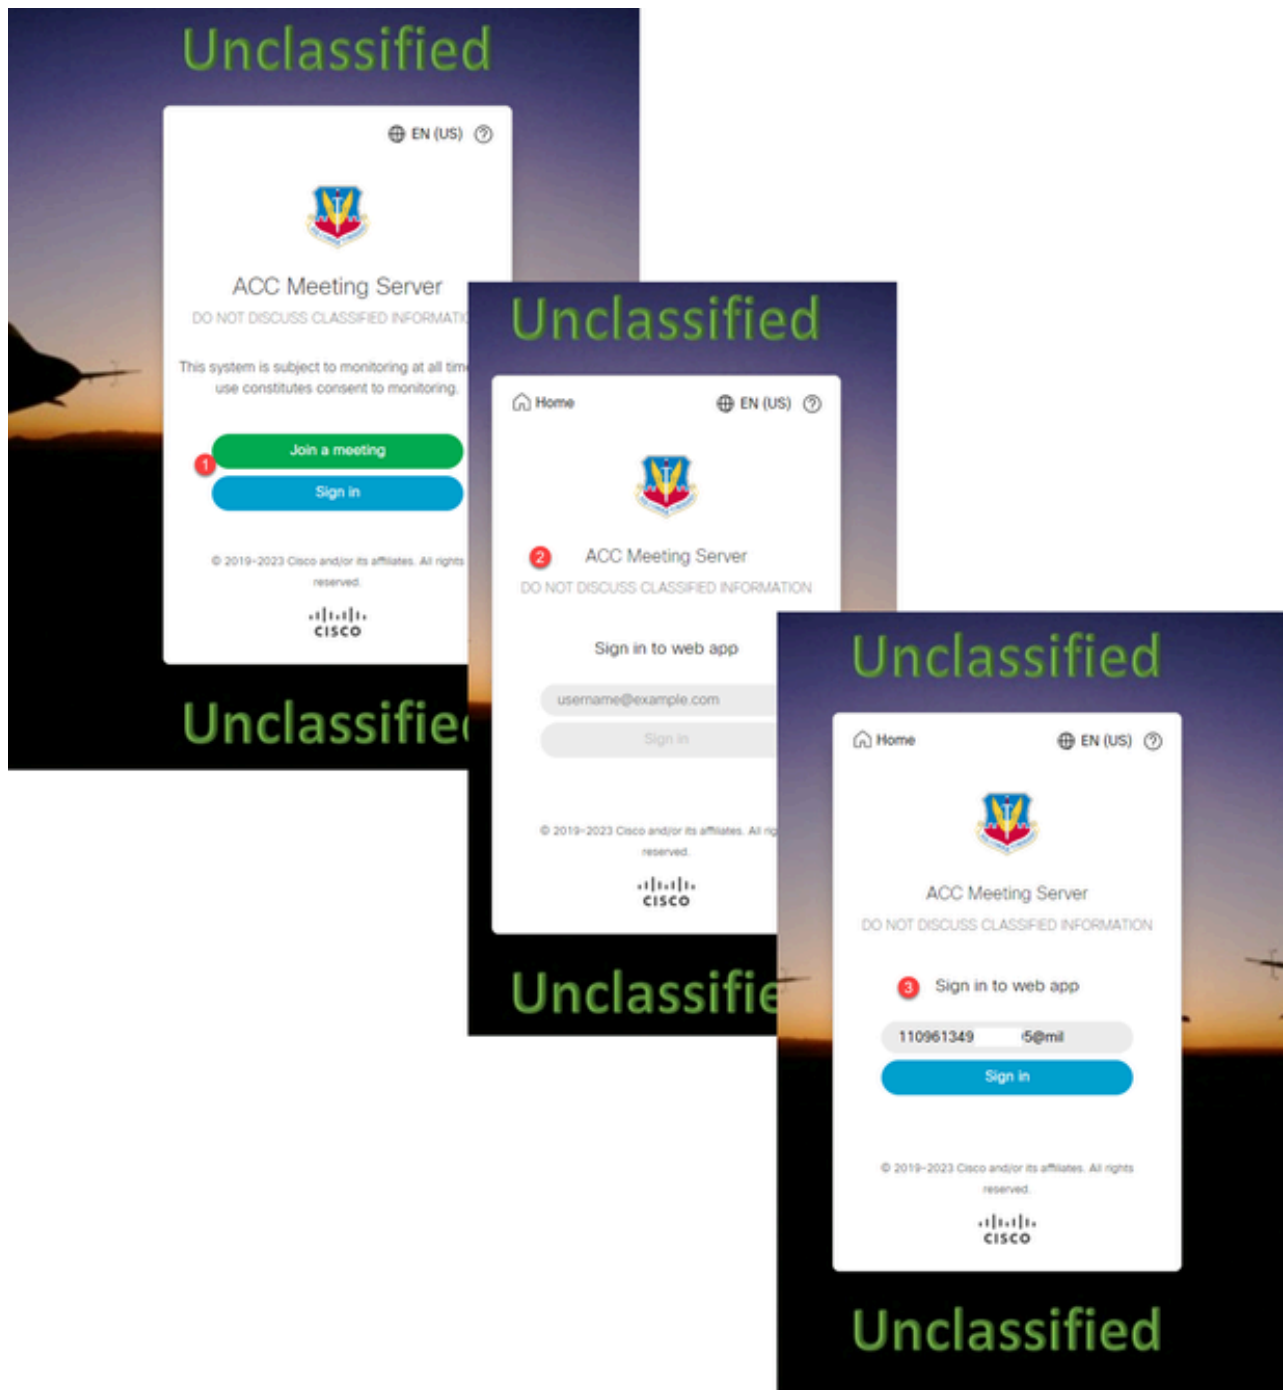

Common Access Card (CAC)

A Common Access Card (CAC) is a smart card that serves as the standard identification for active duty military personnel, DoD civilian employees, and eligible contractor personnel.

Here is the entire sign-in process for users who use CAC Cards:

1. Turn on PC, and stick in CAC card
2. Log in (pick cert sometimes), and enter Pin
3. Open browser
4. Navigate to the join URL and see the **Join a meeting** or **Sign In** options
5. Sign in: Enter the username that is configured as jidMapping and the Active Directory will be expecting from a CAC login
6. Hit sign in
7. ADFS page comes up briefly and is auto populated
8. User will be logged in at this point

Configure **jidMapping** (this is the users sign in name) in **Ldapmapping** the same as what ADFS uses for CAC card. **\$userPrincipalName\$** for example (case sensitive)

Also set the same LDAP attribute for the **authenticationIdMapping** to match the attribute which is used in the Claim rule in ADFS.

Here, the claim rule shows it will send **\$userPrincipalName\$** back to CMS as the UID.

Edit Rule - webbridge sso ✕

You can configure this rule to send the values of LDAP attributes as claims. Select an attribute store from which to extract LDAP attributes. Specify how the attributes will map to the outgoing claim types that will be issued from the rule.

Claim rule name:

Rule template: Send LDAP Attributes as Claims

Attribute store:

Mapping of LDAP attributes to outgoing claim types:

	LDAP Attribute (Select or type to add more)	Outgoing Claim Type (Select or type to add more)
▶	User-PrincipalName	uid
⊕		

Testing SSO Log in via WebApp

Now that SSO has been configured, you can test the server:

1. Navigate to Webbridge URL for the Web App and select the **Sign in** button.

Cisco Meeting Server

web app

Join meetings, anywhere, anytime

Join a meeting

Sign in

© 2020 Cisco and/or its affiliates. All rights reserved.

2. The user is presented with the option to input their user name (notice no password option on this page).

Cisco Meeting Server

web app

Sign in to web app

Sign in

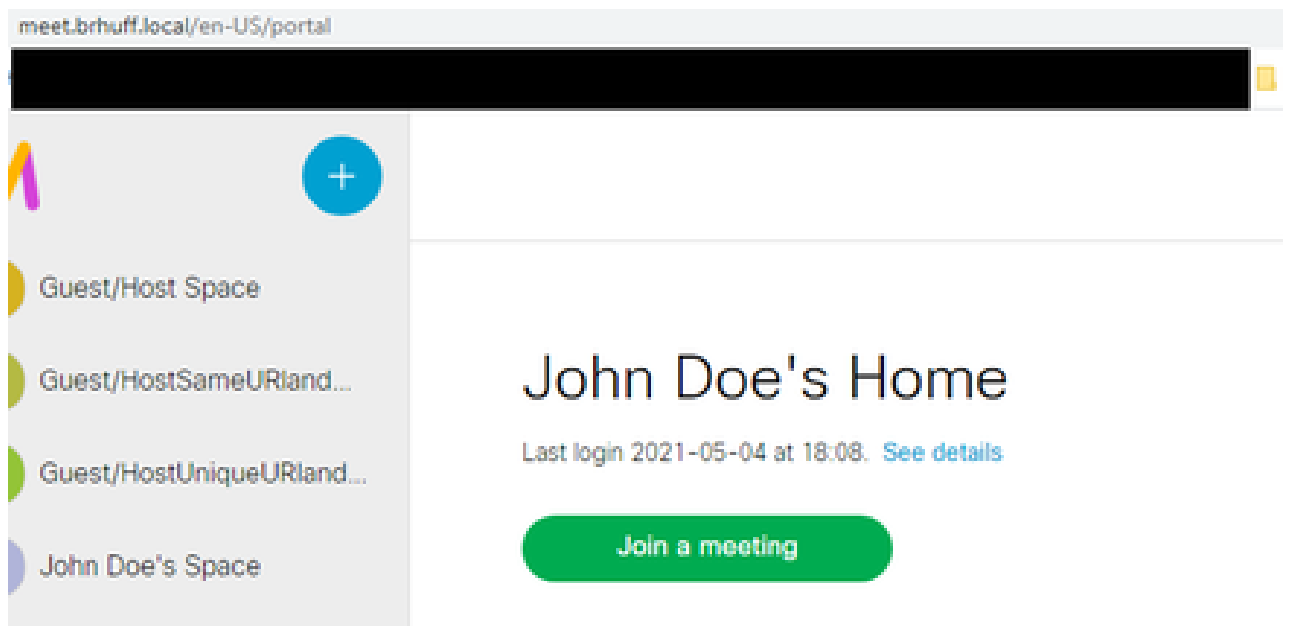

© 2020 Cisco and/or its affiliates. All rights reserved.

3. The user is then redirected to the ADFS page (after inputting user details) where the user must input their credentials to authenticate to IdP.

4. The user, after inputting and validating credentials with the IdP is redirected with the token to access the Web App home page:

Troubleshooting

Basic Troubleshooting

For basic troubleshooting of any SSO issue:

1. Ensure that the constructed Metadata for the Webbridge3 used to import as a Relying Trust in IdP is configured correctly and the URL configured matches exactly as the ssoServiceProviderAddress in the config.json.
2. Ensure the metadata provided by the IdP and zipped into the Webbridge3 sso configuration file is the latest from the IdP, as if there were any changes to the server host name, certificates, and so on, it needs to be re-exported and zipped into the configuration file.
3. If using signing and encrypting private keys to encrypt data, ensure that the correct matching keys are part of the sso_XXXX.zip file you uploaded to webbridge. If possible, attempt to test without the optional private keys to see if SSO works without this encrypted option.
4. Ensure that the config.json is configured with the correct details for SSO domains, Webbridge3 URL AND expected authenticationmapping to match from the SAMLResponse.

It would also be ideal to attempt the troubleshooting from the log perspective:

1. When navigating to the Webbridge URL, place **?trace=true** at the end of the URL to enable a verbose logging on the CMS syslog. (ex: <https://join.example.com/en-US/home?trace=true>).
2. Run the **syslog follow** on the Webbridge3 server to capture live during testing or run the test with the trace option appended to the URL and collect the logbundle.tar.gz from the Webbridge3 and CMS Callbridge servers. If webbridge and callbridge are on the same server, this requires only the single logbundle.tar.gz file.

Microsoft ADFS failure codes

Sometimes, there is a failure for the SSO process that can result in a failure for the IdP configuration or its communication with the IdP. If using the ADFS, it would be ideal to review the next link to confirm the failure being seen and take remediation action:

[Microsoft Status codes](#)

An example of this is:

```
client_backend: ERROR : SamlManager : SAML Authentication request _e135ca12-4b87-4443-abe1-30d396590d58 failed with reason: urn:oasis:names:tc:SAML:2.0:status:Responder
```

This error indicates that per the previous documentation, the failure occurred due to the IdP or ADFS and thus required to be handled by the Administrator of the ADFS to resolve.

Failed to obtain authenticationID

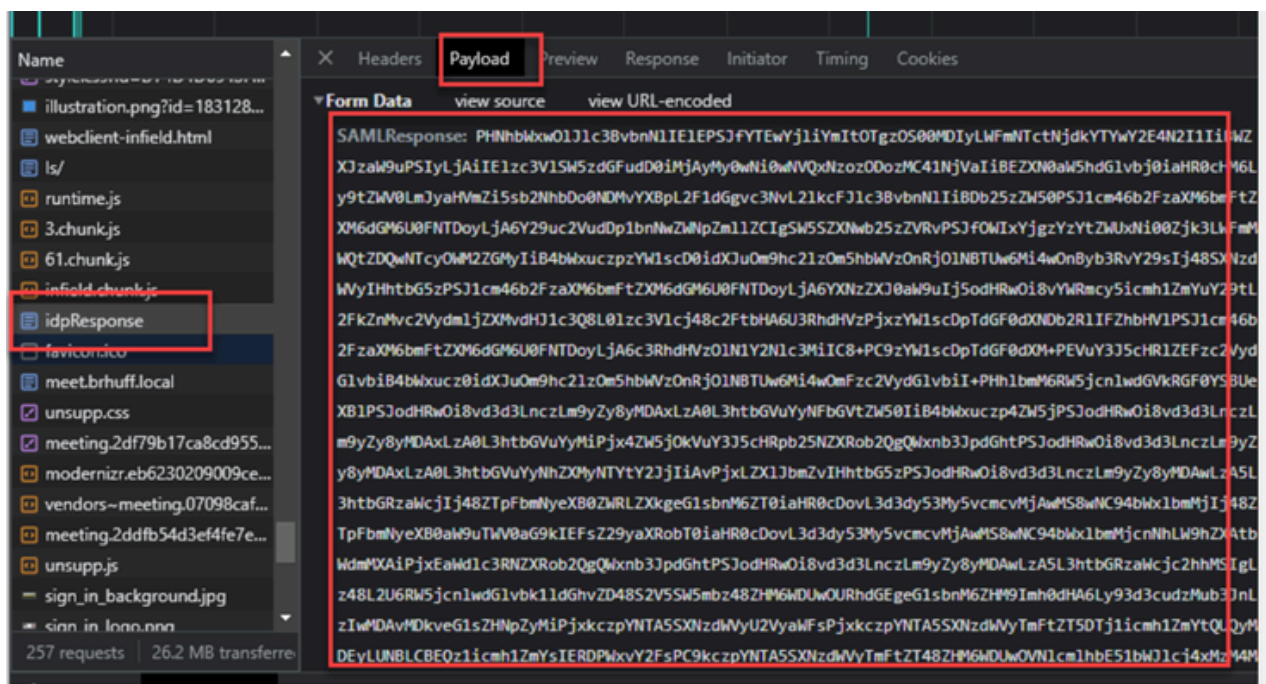

There can be instances in which during the exchange of SAMLResponse back from the IdP, the Webbridge can display this error message in the logs with a failure in logging in via SSO:

```
client_backend: INFO : SamlManager : [57dff9e3-862e-4002-b4fa-683e4aa6922c] Failed obtaining an authenticationId
```

What this indicates is that when reviewing the SAMLResponse data passed back from the IdP during the authentication exchange, the Webbridge3 did not find a valid matching attribute in the response compared to its config.json for the **authenticationId**.

If the communication is not encrypted with the use of the sign and encryption private keys, the SAML Response can be extracted from the Developer Tools Network Logging via a web browser and decoded using base64. If the response is encrypted, you can request the decrypted SAML response from the IdP side.

In the developer tools network logging output, also referred to as the HAR data, look for idpResponse under the name column and select **Payload** to see the SAML response. As mentioned previously, this can be decoded using base64 decoder.

When receiving the SAMLResponse data, check the section of **<AttributeStatement>** to locate the attribute names sent back and within this section you can find the claim types configured and sent from the IdP. For example:

```
<AttributeStatement>
<Attribute Name="<URL for commonname">
<AttributeValue>testuser1</AttributeValue>
</Attribute>
<Attribute Name="<URL for NameID">
<AttributeValue>testuser1</AttributeValue>
</Attribute>
<Attribute Name="uid">
<AttributeValue>testuser1</AttributeValue>
```

```
</Attribute>
</AttributeStatement>
```

Reviewing the previous names, you can check the **<AttributeName>** under the Attribute Statement section and compare each value to what is set in the **authenticationIdmapping** section of the SSO **config.json**.

In the previous example, you can see that configuration for the **authenticationIdMapping** does NOT match exactly what is passed and thus results in the failure to locate a matching authenticationId:

```
authenticationIdMapping : http://example.com/claims/NameID
```

In order to resolve this issue, there are two possible methods to attempt:

1. The IdP Outgoing claim rule can be updated to have a matching claim that matches exactly what is configured in **authenticationIdMapping** of the config.json on the Webbridge3. (Claim rule added on IdP for <http://example.com/claims/NameID>)
OR
2. The config.json can be updated on the Webbridge3 to have the 'authenticationIdMapping' matching exactly what is configured as one of the Outgoing claim rules configured on the IdP. (That is 'authenticationIdMapping' to be updated to match one of the attribute names, which could be "uid", "<URL>/NameID", or "<URL>/CommonName". As long as it matches (exactly) the expected value configured on the Callbridge API when passed)

No assertion passed/matched in validation

Sometimes, during the exchange of the SAMLResponse from the IdP, the Webbridge displays this error indicating there is a failure in matching the assertion and skips any assertions that do not match the server configuration:

```
client_backend: ERROR : SamlManager : No assertions passed the validation
client_backend: INFO : SamlManager : Skipping assertion without us in the allowed audience
```

What this error indicates is that when reviewing the SAMLResponse from the IdP, the Webbridge failed to locate any matching assertions and thus skipped non-matching failures and ultimately resulted in a failed SSO log in.

In order to locate this issue, it is ideal to review the SAMLResponse from the IdP. If the communication is not encrypted with the use of the sign and encryption private keys, the SAML Response can be extracted from the **Developer Tools Network Logging** via a web browser and decoded using base64. If the response is encrypted, you can request the decrypted SAML response from the IdP side.

When reviewing the SAMLResponse data, looking at the **<AudienceRestriction>** section of the response, you can find all audiences that this response is restricted for:

```
<Conditions NotBefore=2021-03-30T19:35:37.071Z NotOnOrAfter=2021-03-30T19:36:37.071Z>
<AudienceRestriction>
<Audience>https://cisco.example.com</Audience>
</AudienceRestriction>
</Conditions>
```

Using the value in the **<Audience>** section (<https://cisco.example.com>) you can compare it to

the **ssoServiceProviderAddress** in the config.json of the Webbridge configuration and validate if it is an exact match. For this example, you can see that reason for the failure is the Audience does NOT match the Service provider address in the configuration, because it has the appended **:443**:

ssoServiceProviderAddress : <https://cisco.example.com:443>

This requires an exact match between these to not result in a failure such as this. For this example. the fix would be to either of these two methods:

1. The **:443** could be removed from the address in the ssoServiceProviderAddress section of the config.json, so that it matches the **Audience** field provided in the SAMLResponse from the IdP.

OR

2. The metadata OR relying trust party for Webbridge3 in the IdP can be updated to have the **:443** appended to the URL. (If the metadata is updated, it must be imported again as a **Relying Trust Party** on the ADFS. However, if you modify the Relying Trust Party from the IdP wizard directly, it does not need to be imported again.)

), webbridge checks that the domain used matches one in the config.json file, then sends the SAML information to the client, telling the client where to connect to for authentication. The client will attempt to connect to the IdP that is in the SAML token. In the example below, the browser shows this page because it cannot reach the ADFS server.

Error on Client browser

Scenario 2:

User attempted to sign in using domain that is not in the SSO zip file on webbridge signin page. Client sends in a tokenRequest with a payload of the username the user entered. Webbridge stops the login attempt immediately.

CMS Webbridge traces (while ?trace=true is used)

Mar 18 14:54:52.698 user.err cmscb3-1 client_backend: ERROR : SamlManager : Invalid SSO login attempt

Mar 18 14:54:52.698 user.info cmscb3-1 client_backend: INFO : SamlManager : [3f93fd14-f4c9-4e5e-94d5-49bf6433319e] Failed finding an SSO in SAML Token Request

Scenario 3:

User has entered the correct username and is presented the SSO sign in page. The user enters the correct username and password here too, but still gets Sign in Failed

CMS Webbridge traces (while ?trace=true is used)

Mar 19 16:39:17.714 user.info cmscb3-1 client_backend: INFO : SamlManager : [ef8fe67f-685c-4a81-9240-f76239379806] Matched SSO sso_2024.zip in SAML Token Request

Mar 19 16:39:17.714 user.info cmscb3-1 client_backend: INFO : SamlManager : [ef8fe67f-685c-4a81-9240-f76239379806] Attempting to find SSO in SAML IDP Response

Mar 19 16:39:17.720 user.err cmscb3-1 client_backend: ERROR : SamlManager : No authenticationId mapped element found in signed SAML Assertions

Mar 19 16:39:17.720 user.info cmscb3-1 client_backend: INFO : SamlManager : [ef8fe67f-685c-4a81-9240-f76239379806] Failed obtaining an authenticationID

The cause for scenario 3 was the claim rule in the IdP was using a claim type that did not match the authenticationIdMapping in the config.json file used in the SSO zip file that was uploaded to webbridge. Webbridge is looking at the SAML response and expects the attribute name to match what is configured in the config.json.

Edit Rule - Webbridge3

You can configure this rule to send the values of LDAP attributes as claims. Select an attribute store from which to extract LDAP attributes. Specify how the attributes will map to the outgoing claim types that will be issued from the rule.

Claim rule name:
Webbridge3

Rule template: Send LDAP Attributes as Claims

Attribute store:
Active Directory

Mapping of LDAP attributes to outgoing claim types:

	LDAP Attribute (Select or type to add more)	Outgoing Claim Type (Select or type to add more)
▶	E-Mail-Addresses	E-Mail Address
•		

```
1 {  
2   "authenticationIdMapping" : "uid",  
3   "ssoServiceProviderAddress" : "https://meet.brhuff.local:443",  
4   "supportedDomains" : ["brhuff.com"]  
5 }
```

config.json example

Username is not Recognized

Scenario 1:

User signed in with wrong username (Domain matches what is in the SSO zip file that was uploaded to webbridge3, but user does not exist)

in CMS ldapmapping does not match the configured LDAP attribute used for claim rule in ADFS. The line below saying "**Successfully obtained authenticationID:darmckin@brhuff.com**" is saying ADFS has claim rule configured with attribute that gets darmckin@brhuff.com from active directory, but the AuthenticationID in CMS **API > Users** shows it is expecting darmckin. In the CMS ldapMappings, the **AuthenticationID** is configured as **\$sAMAccountName\$**, but the claim rule in ADFS is configured to send the **E-Mail-Addresses**, so this does not match.

How to fix this:

Do either of the following:

1. Change the AuthenticationID in the CMS ldapmapping to match what is used in the Claim rule on ADFS and perform a new sync
2. Change the LDAP Attribute used in ADFS Claim rule to match what is configured in CMS ldapmapping
