## Fields

### DEFAULT\_FILE\_NAME\_BASE

```
public static final java.lang.String DEFAULT_FILE_NAME_BASE
```

**DEFAULT\_FILE\_NAME\_EXTENSION**

```
public static final java.lang.String DEFAULT_FILE_NAME_EXTENSION
```

**DIR\_BASE\_NAME\_NUM\_SEPERATOR**

```
public static final char DIR_BASE_NAME_NUM_SEPERATOR
```

**MIN\_FILE\_SIZE**

```
public static final int MIN_FILE_SIZE
```

**MIN\_FILES**

```
public static final int MIN_FILES
```

**ROLLOVER\_THRESHOLD**

```
public static final int ROLLOVER_THRESHOLD
```

## Constructors

**LogFileTraceWriter(String, String, int, int)**

```
public LogFileTraceWriter(java.lang.String fileNameBase,
    java.lang.String fileNameExtension,
    int maxFiles,
    int maxFileSize) throws IOException
```

Default constructor for LogFileTraceWriter that rotates among an arbitrary number of files with tracing for all levels. Since a path and Directory Base name is not specified, it writes the files to the current directory without any sub directories.

Throws:

java.io.IOException

**LogFileTraceWriter(String, String, String, String, int, int, boolean)**

```
public LogFileTraceWriter(java.lang.String path,
    java.lang.String dirNameBase,
    java.lang.String fileNameBase,
    java.lang.String fileNameExtension,
    int maxFiles,
    int maxFileSize,
    boolean useSameDir) throws IOException
```

Default constructor for LogFileTraceWriter that rotates among an arbitrary number of files with tracing for all levels.

Throws:

java.io.IOException

**LogFileTraceWriter(String, String, String, String, int, int, int, boolean)**

```
public LogFileTraceWriter(java.lang.String path,
    java.lang.String dirNameBase,
    java.lang.String fileNameBase,
```

```

    java.lang.String fileNameExtension,
    int maxFiles,
    int maxFileSize,
    int maxTraceLevel,
    boolean useSameDir) throws IOException

```

Constructs a `LogFileTraceWriter` that rotates among an arbitrary number of files storing them in a specified directory.

Throws:

`java.io.IOException`

## Methods

### **doClose()**

```
protected void doClose()
```

Closes this `OutputStream`. Any log file that is currently open will be closed as well.

Overrides:

`doClose` in class [BaseTraceWriter](#), on page 693

### **doFlush()**

```
protected void doFlush()
```

Overrides:

`doFlush` in class [BaseTraceWriter](#), on page 693

### **doPrintln(String, int)**

```
protected void doPrintln(java.lang.String message,
    int messageNumber)
```

**Description copied from class:** `com.cisco.services.tracing.BaseTraceWriter`

Must be implemented by the various `TraceWriters` extending `BaseTraceWriter` to provide the specific tracing functionality

Overrides:

`doPrintln` in class [BaseTraceWriter](#), on page 693

### **getCurrentFile()**

```
public int getCurrentFile()
```

Returns:

the `CurrentFile` property

### **getFileExtension()**

```
public java.lang.String getFileExtension()
```

Returns:

the `FileExtension` property

**getFileNameBase()**

```
public java.lang.String getFileNameBase()
```

Returns:

the FileNameBase property

**getHeader()**

```
public java.lang.String getHeader()
```

Get the header string that will be written at the beginning of each log file.

Returns:

the Header Property

**getMaxFiles()**

```
public int getMaxFiles()
```

Returns:

the MaxFiles property

**getMaxFileSize()**

```
public int getMaxFileSize()
```

Returns:

the MaxFileSize property

**setHeader(String)**

```
public void setHeader(java.lang.String header)
```

Set the constant header string that will be written at the beginning of every file, trace writing continues from the next line after the header is written. If `setHeader` is called after a file output has started, it will take effect from the next file to be written.

Usage:

```
tm = TraceManagerFactory.registerModule(this);  
tw = newLogFileTraceWriter("trace", "log", 10, 1024*1024);  
tw.setHeader(header);  
tm.getTraceWriterManager().addTraceWriter(tw);
```

## OutputStreamTraceWriter

OutputStreamTraceWriter wraps an output stream in a TraceWriter. This simplifies adding custom tracing classes that can co-exist with other TraceWriters.

## Declaration

```
public final class OutputStreamTraceWriter extends BaseTraceWriter, on page 693
|
| java.lang.Object
|
| +--com.cisco.services.tracing.BaseTraceWriter
|
| +--com.cisco.services.tracing.OutputStreamTraceWriter
```

## All Implemented Interfaces

## Constructors

### **OutputStreamTraceWriter(int, OutputStream)**

```
public OutputStreamTraceWriter(int maxTraceLevel,  
    java.io.OutputStream outputStream)
```

Default constructor which is auto-flushing

#### **See Also:**

[Trace, on page 712](#)

### **OutputStreamTraceWriter(int, OutputStream, boolean)**

```
public OutputStreamTraceWriter(int maxTraceLevel,  
    java.io.OutputStream outputStream,  
    boolean autoFlush)
```

Create an OutputStreamTraceWriter

#### **See Also:**

[Trace, on page 712](#)

## Methods

### **doClose()**

```
protected void doClose()
```

Overrides:

doClose in class [BaseTraceWriter, on page 693](#)

### **doFlush()**

```
protected void doFlush()
```

Overrides:

doFlush in class [BaseTraceWriter, on page 693](#)

### **doPrintln(String, int)**

```
protected void doPrintln(java.lang.String message, int messageNumber)
```

**Description copied from class:** com.cisco.services.tracing.BaseTraceWriter

Must be implemented by the various TraceWriters extending BaseTraceWriter to provide the specific tracing functionality

Overrides:

doPrintln in class [BaseTraceWriter, on page 693](#)

**getOutputStream()**

```
public java.io.OutputStream getOutputStream()
```

Returns:

the output stream associated with the TraceWriter

## SyslogTraceWriter

SyslogTraceWriter refines the BaseTraceWriter to allow tracing to syslog. Cisco syslog specification calls for sending low level traces to a syslog collector in the form of UDP messages. No buffering is done in this TraceWriter. The SyslogTraceWriter makes an exception to the println() method in that it places a '\0' instead of a System specified line separator to terminate the message packet.

## Declaration

```
public final class SyslogTraceWriter extends BaseTraceWriter, on page 693
    java.lang.Object
    |
    +--com.cisco.services.tracing.BaseTraceWriter
    |
    +--com.cisco.services.tracing.SyslogTraceWriter
```

## All Implemented Interfaces

## Constructors

### **SyslogTraceWriter(int, String)**

```
public SyslogTraceWriter(int port,
    java.lang.Stringcollector)
```

Default SyslogTraceWriter with a max trace level of INFORMATIONAL

#### **See Also:**

[Trace](#), on page 712

### **SyslogTraceWriter(int, String, int)**

```
public SyslogTraceWriter(int port,
    java.lang.Stringcollector,
    intmaxTraceLevel)
```

SyslogTraceWriter with max trace level specified

#### **See Also:**

[Trace](#), on page 712

### **SyslogTraceWriter(int, String, int[])**

```
public SyslogTraceWriter(int port,
    java.lang.Stringcollector,
    int[]traceLevels)
```

SyslogTraceWriter which takes an array of trace levels.

**See Also:**[Trace, on page 712](#)

## Methods

**doClose()**

```
public void doClose()
```

Closes the socket

Overrides:

doClose in class [BaseTraceWriter, on page 693](#)

**doPrintln(String, int)**

```
protected void doPrintln(java.lang.String message,
    int messageNumber)
```

The `SyslogTraceWriter` makes an exception to the `println()` method in that it places a `'\0'` instead of a System specified line separator to terminate the message packet. The portion of the message after a `'\r'` or `'\n'` is ignored

Overrides:

doPrintln in class [BaseTraceWriter, on page 693](#)

**main(String[])**

```
public static void main(java.lang.String[] args)
```

## TraceManagerFactory

The `TraceManagerFactory` class is a class by which applications obtain a `TraceManager` object. The `TraceModule` passed in the constructor is registered in a list. The list can be enumerated using the `getModules()` method.

## Declaration

```
public class TraceManagerFactory
    java.lang.Object
    |
    +-- com.cisco.services.tracing.TraceManagerFactory
```

| <code>clone(), equals(Object), finalize(), getClass(), hashCode(), notify(), notifyAll(), toString(), wait(), wait(), wait()</code> |

## Methods

### **getModules()**

```
public static java.util.Enumeration getModules()
```

Returns an enumeration of the TraceModules registered with this factory.

### **registerModule(TraceModule)**

```
public static com.cisco.services.tracing.TraceManager  
registerModule(com.cisco.services.tracing.TraceModule module)
```

Returns an instance of a TraceManager object. The contained TraceWriterManager will not have any default TraceWriters.

### **registerModule(TraceModule, String[], TraceWriterManager)**

```
public static com.cisco.services.tracing.TraceManager  
registerModule(com.cisco.services.tracing.TraceModule module,  
java.lang.String[] subFacilities,  
com.cisco.services.tracing.TraceWriterManager traceWriterManager)
```

Returns an instance of a TraceManager object. Trace output will be redirected to the TraceWriterManager object specified.

**registerModule(TraceModule, TraceWriterManager)**

```
public static com.cisco.services.tracing.TraceManager
    registerModule(com.cisco.services.tracing.TraceModule module,
        com.cisco.services.tracing.TraceWriterManager traceWriterManager)
```

Returns an instance of a TraceManager object. Trace output will be redirected to the TraceWriterManager object specified.

## Services Tracing Interface Hierarchy

The following interface hierarchy is contained in the com.cisco.services.tracing package.

```
com.cisco.services.tracing.Trace, on page 712
    com.cisco.services.tracing.ConditionalTrace, on page 719
com.cisco.services.tracing.UnconditionalTrace, on page 720

com.cisco.services.tracing.TraceManager, on page 721

com.cisco.services.tracing.TraceModule, on page 725

com.cisco.services.tracing.TraceWriter, on page 726

com.cisco.services.tracing.TraceWriterManager, on page 729
```

## Trace

The Trace interface defines the methods that allow application tracing. Trace also defines the standard trace types as specified by Syslog Trace Logging. Syslog currently defines 8 levels of trace. The severity of the message is indicated in the trace as a number ranging between [0-7] (0 and 7 included). Currently 7 is HIGHEST\_LEVEL and 0 is the LOWEST\_LEVEL trace. All 8 levels are predefined here as static int types for reference in tracing sub-system implementations.

The severities traced are as follows:

- 0 = EMERGENCIES System unusable
- 1 = ALERTS Immediate action needed
- 2 = CRITICAL Critical conditions
- 3 = ERROR Error conditions
- 4 = WARNING Warning conditions
- 5 = NOTIFICATION Normal but significant condition
- 6 = INFORMATIONAL Informational messages only
- 7 = DEBUGGING Debugging messages

## Declaration

```
public interface Trace
```

## All Known Subinterfaces

[ConditionalTrace](#), on page 719 [UnconditionalTrace](#), on page 720

## Fields

### ALERTS

```
public static final int ALERTS
```

The application will continue working on the tasks but all functions may not be operational (one or more devices in the list are not accessible but others in the list can be accessed)

Syslog severity level = 1

### ALERTS\_TRACE\_NAME

```
public static final java.lang.String ALERTS_TRACE_NAME
```

String descriptor for ALERTS trace level

**CRITICAL**

```
public static final int CRITICAL
```

A critical failure, the application cannot accomplish the tasks required due to this failure, e.g.: the application cant open the database to read the device list

Syslog severity level = 2

**CRITICAL\_TRACE\_NAME**

```
public static final java.lang.String CRITICAL_TRACE_NAME
```

String descriptor for CRITICAL trace level

**DEBUGGING**

```
public static final int DEBUGGING
```

Very detailed information regarding errors or processing status that is only generated when DEBUG mode has been enabled

Syslog severity level = 7

**DEBUGGING\_TRACE\_NAME**

```
public static final java.lang.String DEBUGGING_TRACE_NAME
```

String descriptor for the DEBUGGING trace level

**EMERGENCIES**

```
public static final int EMERGENCIES
```

Emergency situation, a system shutdown is necessary

Syslog severity level = 0

**EMERGENCIES\_TRACE\_NAME**

```
public static final java.lang.String EMERGENCIES_TRACE_NAME
```

String descriptor for EMERGENCIES trace level

**ERROR**

```
public static final int ERROR
```

An error condition of some kind has occurred and the user needs to understand the nature of that failure

Syslog severity level = 3

**ERROR\_TRACE\_NAME**

```
public static final java.lang.String ERROR_TRACE_NAME
```

String descriptor for ERROR trace level

**HIGHEST\_LEVEL**

```
public static final int HIGHEST_LEVEL
```

The highest trace level, currently this is DEBUGGING with a trace level of 7

### **INFORMATIONAL**

```
public static final int INFORMATIONAL
```

Information of some form not relating to errors, warnings, audit, or debug

Syslog severity level = 6

### **INFORMATIONAL\_TRACE\_NAME**

```
public static final java.lang.String INFORMATIONAL_TRACE_NAME
```

String descriptor for INFORMATIONAL trace level

### **LOWEST\_LEVEL**

```
public static final int LOWEST_LEVEL
```

The lowest trace level, currently this is EMERGENCIES with a trace level of 0

### **NOTIFICATION**

```
public static final int NOTIFICATION
```

Notification denotes a normal but significant condition

Syslog severity level = 5

### **NOTIFICATION\_TRACE\_NAME**

```
public static final java.lang.String NOTIFICATION_TRACE_NAME
```

String descriptor for NOTIFICATION trace level

### **WARNING**

```
public static final int WARNING
```

Warning that a problem of some form exists but is not keeping the application from completing its tasks

Syslog severity level = 4

### **WARNING\_TRACE\_NAME**

```
public static final java.lang.String WARNING_TRACE_NAME
```

String descriptor for WARNING trace level

## Methods

### **getName()**

```
public java.lang.String getName()
```

Returns:

the name of this Trace object

**getSubFacility()**

```
public java.lang.String getSubFacility()
```

Returns:

the trace subFacility type

**getType()**

```
public int getType()
```

Returns:

the type of trace as specified in Syslog. DEBUGGING, INFORMATIONAL, WARNING, etc.

**isEnabled()**

```
public boolean isEnabled()
```

Returns the state of this Trace object. By default, Trace objects are enabled, that is, `println()` method will always trace. The state may not be changed through this interface, however, this object may implement additional interfaces that allow the state to be changed.

Returns:

true if tracing is enabled, false otherwise

**See Also**

[ConditionalTrace](#), on page 719

**println(Object)**

```
public void println(java.lang.Object object)
```

Prints the string returned by the `Object.toString()` method and terminates the line as defined by the system.

Parameters:

`object` - the object to be printed

**println(String)**

```
public void println(java.lang.String message)
```

Prints a message in the same format as `Trace.print()` and terminates the line as defined by the system.

Parameters:

`message` - the message to be printed

**println(String, Object)**

```
public void println(java.lang.String mnemonic,  
                    java.lang.Object object)
```

Prints the string returned by the `Object.toString()` method and terminates the line as defined by the system.

Parameters:

`object` - the object to be printed

`mnemonic` - the mnemonic mapped to message to be printed

### **println(String, String)**

```
public void println(java.lang.String mnemonic,
    java.lang.Stringmessage)
```

Prints a message in the same format as `Trace.print()` and terminates the line as defined by the system.

Parameters:

`message` - the message to be printed

`mnemonic` - the mnemonic mapped to message to be printed

### **setDefaultMnemonic(String)**

```
public void setDefaultMnemonic(java.lang.String mnemonic)
```

Sets a default mnemonic for all messages printed out to this trace.

Parameters:

`mnemonic`, - a mnemonic string

## ConditionalTrace

The `ConditionalTrace` interface extends the `Trace` interface and defines the methods that allow enabling and disabling of tracing for this particular condition.

Typically, applications obtain one `ConditionalTrace` object for each condition that they need to trace under certain circumstances but not always (for example, AUDIT, INFO, and so on).

## Declaration

```
public interface ConditionalTrace extends Trace, on page 712
```

## All Superinterfaces

**Methods****disable()**

```
public void disable()
```

Disables this condition for tracing.

**enable()**

```
public void enable()
```

Enables this condition for tracing.

**UnconditionalTrace**

The UnconditionalTrace interface extends the Trace interface. Note that because this object extends Trace, its state is enabled by default and it may not be changed.

Typically, applications would obtain one UnconditionalTrace object per each condition that they need to trace always under any circumstances (such as, ERROR, FATAL, and so on).

**Declaration**

```
public interface UnconditionalTrace extends Trace, on page 712
```

**All Superinterfaces**

[Trace](#), on page 712

## TraceManager

The TraceManager interface defines the methods that allow applications trace management.

Typically, an application obtains only one TraceManager object. All Trace objects are created by default: Predefined Trace in accordance with Syslog definitions are:

```
ConditionalTraces:INFORMATIONAL, DEBUGGING, NOTIFICATION, WARNING
UnconditionalTraces:ERROR, CRITICAL, ALERTS, EMERGENCIES
```

### Facilities/Sub-Facilities:

- **Facility**—A code consisting of two or more uppercase letters that indicate the facility to which the message refers. A facility can be a hardware device, a protocol, or a module of the system software.
- **SubFacility**—A code consisting of two or more uppercase letters that indicate the sub-facility to which the message refers. A sub-facility can be a hardware device component, a protocol unit, or a sub-module of the system software.

By default all 8 Conditional and UnConditional Traces are created for the Facility and 8 for each of the subFacilities In order to use the DEBUGGING trace for the parent FACILITY, for example, the application needs to use the `getConditionalTrace(“DEBUGGING”)` method of this object.

In order to use the DEBUGGING trace for the SUBFACILITY, for example, the application needs to use the `getConditionalTrace( SUBFACILITY + “_” + “DEBUGGING” )` method of this object or use the `getConditionalTrace( SUBFACILITY, “DEBUGGING” )` method.

System wide TraceWriterManager is set through the `setTraceWriterManager` method provided by this interface.

The Trace Manager object also allows the application to enable or disable tracing for all trace through the `enableAll()` and `disableAll()` methods.

## Declaration

```
public interface TraceManager
```

## Member Summary

## Methods

### **addSubFacilities(String[])**

```
public void addSubFacilities(java.lang.String[] names)
```

Sets a set of subFacilities for this TraceManager/Facility.

### **addSubFacility(String)**

```
public void addSubFacility(java.lang.String name)
```

Adds a single subFacility for this TraceManager/Facility.

### **disableAll()**

```
public void disableAll()
```

Disables tracing for all Trace objects managed by this TraceManager.

**disableTimeStamp()**

```
public void disableTimeStamp()
```

Disables prefixing a time stamp for every message printed by this TraceManager.

**enableAll()**

```
public void enableAll()
```

Enables tracing for all Trace objects managed by this TraceManager.

**enableTimeStamp()**

```
public void enableTimeStamp()
```

Enables prefixing a time stamp for every message printed by this TraceManager.

**getConditionalTrace(int)**

```
public com.cisco.services.tracing.ConditionalTrace  
    getConditionalTrace(int severity)
```

Creates a new ConditionalTrace object or obtains an existing ConditionalTrace object for this condition.

**getConditionalTrace(String, int)**

```
public com.cisco.services.tracing.ConditionalTrace  
    getConditionalTrace(java.lang.String subFacility,  
        intseverity)
```

Creates a new ConditionalTrace object or obtains an existing ConditionalTrace object for this condition and subFacility

**getName()**

```
public java.lang.String getName()
```

Returns the Facility name for this TraceManager.

**getSubFacilities()**

```
public java.lang.String[] getSubFacilities()
```

Returns the subFacility names for this TraceManager/Facility.

**getTraces()**

```
public java.util.Enumeration getTraces()
```

Returns an enumeration of the Trace objects managed by this TraceManager.

**getTraceWriterManager()**

```
public com.cisco.services.tracing.TraceWriterManager getTraceWriterManager()
```

Returns the TraceWriter used by this TraceManager.

**getUnconditionalTrace(int)**

```
public com.cisco.services.tracing.UnconditionalTrace getUnconditionalTrace(int severity)
```

Creates a new UnconditionalTrace object or obtains an existing UnconditionalTrace object for this condition.

#### **getUnconditionalTrace(String, int)**

```
public com.cisco.services.tracing.UnconditionalTrace
    getUnconditionalTrace(java.lang.String subFacility,
        int severity)
```

Creates a new UnconditionalTrace object or obtains an existing UnconditionalTrace object for this condition and subFacility

#### **removeTrace(Trace)**

```
public void removeTrace(com.cisco.services.tracing.Trace tc)
```

Removes a Trace object given an object.

#### **setSubFacilities(String[])**

```
public void setSubFacilities(java.lang.String[] names)
```

**Deprecated** and replaced with `TraceManager.addSubFacilities` method

Sets a set of subFacilities for this TraceManager/Facility.

#### **setSubFacility(String)**

```
public void setSubFacility(java.lang.String name)
```

**Deprecated** and replaced with `TraceManager.addSubFacility` method

Adds a single subFacility for this TraceManager/Facility.

#### **setTraceWriterManager(TraceWriterManager)**

```
public void setTraceWriterManager(com.cisco.services.tracing.TraceWriterManager twm)
```

Sets the TraceWriter to be used by this TraceManager.

## TraceModule

The TraceModule interface serves two purposes. First, it allows applications to discover the TraceManager object used by other packages that they use. Second, applications that register with the TraceManagerFactory must identify themselves by implementing this interface.

## Declaration

```
public interface TraceModule
```

## All Known Subinterfaces

```
com.cisco.jtapi.extensions.CiscoJtapiPeer
```

## Member Summary

| Member summary   |                                                                                                                 |

| TraceManager     | <a href="#">getTraceManager(), on page 726</a><br>Returns the TraceManager that an object is using for tracing. |
| java.lang.String | <a href="#">getTraceModuleName(), on page 726</a><br>Returns the module name.                                   |

## Methods

### getTraceManager()

```
public com.cisco.services.tracing.TraceManager getTraceManager()
```

Returns the TraceManager that an object is using for tracing.

### getTraceModuleName()

```
public java.lang.String getTraceModuleName()
```

Returns the module name.

## TraceWriter

The TraceWriter interface abstracts the details of trace message output. The TraceWriter uses its enabled method to advertise whether or not the print and println methods will have any effect. Users of TraceWriter should use the value returned by the getEnabled method as an indication of whether they should invoke the print and println methods at all.

## Declaration

```
public interface TraceWriter
```

## All Known Subinterfaces

[TraceWriterManager, on page 729](#)

## All Known Implementing Classes

## Methods

### close()

```
public void close()
```

Releases any resources associated by this TraceWriter.

### flush()

```
public void flush()
```

Forces output of any messages that have been printed using the println method

### getDescription()

```
public java.lang.String getDescription()
```

Returns:

a short description of this TraceWriter

**getEnabled()**

```
public boolean getEnabled()
```

Returns whether the `println` method will print anything or not. A closed `TraceWriter` will always return `false` from this method.

Returns:

true if this `TraceWriter` is enabled, false if not

**getName()**

```
public java.lang.String getName()
```

Returns:

the name of this `TraceWriter`

**getTraceLevels()**

```
public int[] getTraceLevels()
```

Returns:

the array of trace levels that will be traced by this `TraceWriter`

**println(String, int)**

```
public void println(java.lang.String message,  
                    int severity)
```

Prints the specified string followed by a carriage return. The concrete `TraceWriter` class will use the severity to block out messages from a particular stream. Each trace writer has a notion of the highest level trace it traces.

Parameters:

`message` - the string to print

`severity` - of the trace.

**See Also**

[Trace, on page 712](#)

**setTraceLevels(int[])**

```
public void setTraceLevels(int[] levels)
```

set the trace levels that will be traced by this `TraceWriter`

Parameters:

`int[]` - levels

**See Also**

[Trace, on page 712](#)

# TraceWriterManager

TraceWriterManager contains the list of TraceWriter objects that are used to implement the tracing. The list is populated at startup from the switches in a .ini file. A LogFileTraceWriter, a ConsoleTraceWriter, and a SyslogTraceWriter are available. Users can override the existing TraceWriters by setting a user implemented TraceWriter[] or adding to the existing TraceWriters. This makes it possible to add other TraceWriters that can function along with existing trace writers.

## Declaration

```
public interface TraceWriterManager extends TraceWriter, on page 726
```

## All Superinterfaces

[TraceWriter](#), on page 726

## Methods

### **addTraceWriter(TraceWriter)**

```
public void addTraceWriter(com.cisco.services.tracing.TraceWriter traceWriter)
```

Add another TraceWriter to the array

Parameters:

TraceWriter - to be added to the list

### **getTraceWriters()**

```
public com.cisco.services.tracing.TraceWriter[] getTraceWriters()
```

Returns:

the array of TraceWriters in the manager

### **removeTraceWriter(TraceWriter)**

```
public void removeTraceWriter(com.cisco.services.tracing.TraceWriter traceWriter)
```

Remove the TraceWriter from the array in the manager

### **setTraceWriters(TraceWriter[])**

```
public void setTraceWriters(com.cisco.services.tracing.TraceWriter[] traceWriters)
```

Implementations can use this method to override or enhance the provided TraceWriters

Parameters:

set - the array of TraceWriters.

## Tracing Implementation Class Hierarchy

The following tracing implementation class hierarchy is contained in the `com.cisco.services.tracing.implementation` package.

```
java.lang.Object
  com.cisco.services.tracing.implementation.TraceImpl, on page 731 (implements
    com.cisco.services.tracing.Trace)
  com.cisco.services.tracing.implementation.ConditionalTraceImpl, on page 733 (implements
    com.cisco.services.tracing.ConditionalTrace)
  com.cisco.services.tracing.implementation.UnconditionalTraceImpl, on page 734 (implements
    com.cisco.services.tracing.UnconditionalTrace)
  com.cisco.services.tracing.implementation.TraceManagerImpl, on page 735 (implements
    com.cisco.services.tracing.TraceManager)
  com.cisco.services.tracing.implementation.TraceWriterManagerImpl, on page 739 (implements
    com.cisco.services.tracing.TraceWriterManager)
```

# TraceImpl

## Declaration

```
public abstract class TraceImpl  
    extends java.lang.Object  
    implements Trace
```

## All Implemented Interfaces

[Trace](#), on page 712

## Methods

### **println**

```
public final void println(java.lang.String message)
```

Description copied from interface: Trace

Prints a message in the same format as Trace.print() and terminates the line as defined by the system.

#### **Specified by:**

println in interface Trace

#### **Parameters:**

message - the message to be printed

### **println**

```
public final void println(java.lang.String mnemonic, java.lang.String message)
```

Description copied from interface: Trace

Prints a message in the same format as Trace.print() and terminates the line as defined by the system.

#### **Specified by:**

println in interface Trace

#### **Parameters:**

mnemonic - the mnemonic mapped to message to be printed

message - the message to be printed

### **println**

```
public final void println(java.lang.Object object)
```

Description copied from interface: Trace

Prints the string returned by the `Object.toString()` method and terminates the line as defined by the system.

**Specified by:**

`println` in interface `Trace`

**Parameters:**

object - the object to be printed

**println**

public final void **println**(java.lang.String mnemonic, java.lang.Object object)

Description copied from interface: `Trace`

Prints the string returned by the `Object.toString()` method and terminates the line as defined by the system.

**Specified by:**

`println` in interface `Trace`

**Parameters:**

mnemonic - the mnemonic mapped to message to be printed

object - the object to be printed

**getName**

public final java.lang.String **getName**()

Description copied from interface: `Trace`

Returns the name of this `Trace` object.

**Specified by:**

`getName` in interface `Trace`

**Returns:**

the name of this `Trace` object

**setDefaultMnemonic**

public final void **setDefaultMnemonic**(java.lang.String mnemonic)

Description copied from interface: `Trace`

Sets a default mnemonic for all messages printed out to this trace.

**Specified by:**

`setDefaultMnemonic` in interface `Trace`

**Parameters:**

mnemonic - a mnemonic string

**getType**

public int **getType**()

Description copied from interface: Trace

Returns the type of trace.

**Specified by:**

getType in interface Trace

**Returns:**

the trace severity as specified in Syslog. DEBUGGING, INFORMATIONAL, WARNING, etc.

**getSubFacility**

```
public java.lang.String getSubFacility()
```

Description copied from interface: Trace

Returns the subFacility of trace

**Specified by:**

getSubFacility in interface Trace

**Returns:**

the trace subFacility type

## Inherited Methods

isEnabled

# ConditionalTraceImpl

## Declaration

```
public final class ConditionalTraceImpl
```

```
extends TraceImpl
```

```
implements ConditionalTrace
```

## All Implemented Interfaces

ConditionalTrace, Trace

## Methods

**enable**

```
public void enable()
```

Description copied from interface: ConditionalTrace

Enables this condition for tracing.

**Specified by:**

enable in interface ConditionalTrace

**disable**

public void **disable**()

Description copied from interface: ConditionalTrace

Disables this condition for tracing.

**Specified by:**

disable in interface ConditionalTrace

**isEnabled**

public boolean **isEnabled**()

Description copied from interface: Trace

Returns the state of this Trace object. By default, Trace objects are enabled, that is, println() method will always trace. The state may not be changed through this interface, however, this object may implement additional interfaces that allow the state to be changed.

**Specified by:**

isEnabled in interface Trace

**Returns:**

true if tracing is enabled, false otherwise

**See Also:**

ConditionalTrace

## Inherited Methods

Inherited methods from class java.lang.Object are: clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait.

## UnconditionalTraceImpl

### Declaration

```
public final class UnconditionalTraceImpl
```

```
extends TraceImpl
```

```
implements UnconditionalTrace
```

## All Implemented Interfaces

Trace, UnconditionalTrace

## Methods

### isEnabled

public boolean **isEnabled**()

Description copied from interface: Trace

Returns the state of this Trace object. By default, Trace objects are enabled, that is, `println()` method will always trace. The state may not be changed through this interface, however, this object may implement additional interfaces that allow the state to be changed.

### Specified by:

isEnabled in interface Trace

### Returns:

true if tracing is enabled, false otherwise

### See Also:

ConditionalTrace

## Inherited Methods

Inherited methods from class `java.lang.Object` are: `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`.

## TraceManagerImpl

The `TraceManagerImpl` class implements the `TraceManager` interface.

## Declaration

```
public class TraceManagerImpl extends java.lang.Object
    java.lang.Object
    |
    +--com.cisco.services.tracing.implementation.TraceManagerImpl
```

## All Implemented Interfaces

[TraceManager](#), on page 721

## Constructors

```
public TraceManagerImpl(java.lang.String moduleName, java.lang.String[] subFacilities,
    TraceWriterManager traceWriterManager)
```

```
public TraceManagerImpl(java.lang.String moduleName, TraceWriterManager traceWriterManager)
```

## Methods

### **getConditionalTrace**

```
public ConditionalTrace getConditionalTrace(int severity)
```

**Description copied from interface:** TraceManager

Creates a new ConditionalTrace object or obtains an existing ConditionalTrace object for this condition.

Specified by:

```
getConditionalTrace in interface TraceManager
```

### **getConditionalTrace**

```
public ConditionalTrace getConditionalTrace(java.lang.String subFacility,
    int severity)
```

**Description copied from interface:** TraceManager

Creates a new ConditionalTrace object or obtains an existing ConditionalTrace object for this condition and subFacility

Specified by:

```
getConditionalTrace in interface TraceManager
```

### **getUnconditionalTrace**

```
public UnconditionalTrace getUnconditionalTrace(int severity)
```

**Description copied from interface:** TraceManager

Creates a new UnconditionalTrace object or obtains an existing UnconditionalTrace object for this condition.

Specified by:

```
getUnconditionalTrace in interface TraceManager
```

### **getUnconditionalTrace**

```
public UnconditionalTrace getUnconditionalTrace(java.lang.String subFacility,
    int severity)
```

**Description copied from interface:** TraceManager

Creates a new UnconditionalTrace object or obtains an existing UnconditionalTrace object for this condition and subFacility

Specified by:

```
getUnconditionalTrace in interface TraceManager
```

**getTraceWriterManager**

```
public TraceWriterManager getTraceWriterManager()
```

**Description copied from interface:** TraceManager

Returns the TraceWriter used by this TraceManager.

Specified by:

```
getTraceWriterManager in interface TraceManager
```

**setTraceWriterManager**

```
public void setTraceWriterManager(TraceWriterManagerout)
```

**Description copied from interface:** TraceManager

Sets the TraceWriter to be used by this TraceManager.

Specified by:

```
setTraceWriterManager in interface TraceManager
```

**removeTrace**

```
public void removeTrace(Tracetc)
```

**Description copied from interface:** TraceManager

Removes a Trace object given an object.

Specified by:

```
removeTrace in interface TraceManager
```

**getTraces**

```
public java.util.Enumeration getTraces()
```

**Description copied from interface:** TraceManager

Returns an enumeration of the Trace objects managed by this TraceManager.

Specified by:

```
getTraces in interface TraceManager
```

**enableAll**

```
public void enableAll()
```

**Description copied from interface:** TraceManager

Enables tracing for all Trace objects managed by this TraceManager.

Specified by:

```
enableAll in interface TraceManager
```

**disableAll**

```
public void disableAll()
```

**Description copied from interface:** TraceManager

Disables tracing for all Trace objects managed by this TraceManager.

Specified by:

```
disableAll in interface TraceManager
```

### **getName**

```
public java.lang.String getName()
```

**Description copied from interface:** TraceManager

Returns the Facility name for this TraceManager.

Specified by:

```
getName in interface TraceManager
```

### **enableTimeStamp**

```
public void enableTimeStamp()
```

**Description copied from interface:** TraceManager

Enables prefixing a time stamp for every message printed by this TraceManager.

Specified by:

```
enableTimeStamp in interface TraceManager
```

### **disableTimeStamp**

```
public void disableTimeStamp()
```

**Description copied from interface:** TraceManager

Disables prefixing a time stamp for every message printed by this TraceManager.

Specified by:

```
disableTimeStamp in interface TraceManager
```

### **getSubFacilities**

```
public java.lang.String[] getSubFacilities()
```

Returns the subFacility names for this TraceManager/Facility.

Specified by:

```
getSubFacilities in interface TraceManager
```

### **addSubFacilities**

```
public void addSubFacilities(java.lang.String[]names)
```

Adds subFacilities for this TraceManager/Facility.

Specified by:

```
addSubFacilities in interface TraceManager
```

**addSubFacility**

```
public void addSubFacility(java.lang.Stringname)
```

Adds a subFacility for this TraceManager/Facility.

Specified by:

```
addSubFacility in interface TraceManager
```

## Deprecated

**getSubFacilities(java.lang.String[]names)**

Replaced by addSubFacilities(String[]).

**setSubFacility(java.lang.Stringname)**

Replaced by addSubFacility(String).

## Inherited Methods

Inherited methods from class java.lang.Object are: clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait.

## TraceWriterManagerImpl

TraceWriterManager contains the list of TraceWriter objects that are used to implement the tracing. The list is populated at startup from the switches in a .ini file. A LogFileTraceWriter, a ConsoleTraceWriter, and a SyslogTraceWriter are available. Users can override the existing TraceWriters by setting a user implemented TraceWriter[] or adding to the existing TraceWriters. This makes it possible to add other traceWriters that can function along with existing trace writers.

---

**Note** Methods inherited from class java.lang.Object are clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait.

---

## Declaration

```
public class TraceWriterManagerImpl extends java.lang.Object implements TraceWriterManager
java.lang.Object
com.cisco.services.tracing.implementation.TraceWriterManagerImpl
```

## All Implemented Interfaces

TraceWriter, TraceWriterManager

## Constructors

### TraceWriterManagerImpl

```
public TraceWriterManagerImpl()
```

Creates a TraceWriterManagerImpl with a zero length TraceWriter array .

## Methods

### setTraceWriters

```
public void setTraceWriters(TraceWriter[]traceWriters)
```

Overrides the existing TraceWriters with a new user supplied set .

Specified by:

```
setTraceWriters in interface TraceWriterManager
```

Parameters:

traceWriters - An array of TraceWriters.

### getTraceWriters

```
public TraceWriter[] getTraceWriters()
```

Returns the array of TraceWriters currently in use .

Specified by:

```
getTraceWriters in interface TraceWriterManager
```

Returns:

The array of TraceWriters in the manager.

### addTraceWriter

```
public void addTraceWriter(TraceWritertw)
```

Add this TraceWriter to the array of trace writers

Specified by:

```
addTraceWriter in interface TraceWriterManager
```

Parameters:

tw - TraceWriter to be added to the list

### removeTraceWriter

```
public void removeTraceWriter(TraceWritertw)
```

Remove the Tracewriter from the array of trace writers.

Specified by:

```
removeTraceWriter in interface TraceWriterManager
```

**println**

```
public void println(java.lang.Stringmessage, intseverity)
```

All traces invoke this method. A trace supplies its severity along with the message. Traces below the threshold severity of the TraceWriter are allowed. Eg. If the Threshold severity is set to INFORMATIONAL (level = 6) DEBUG traces will not be passed by the TraceWriter. The severity level is set in the constructor of the TraceWriter

Specified by:

println in interface TraceWriter

Parameters:

message - The string to print

severity - The severity of the trace.

See Also:

Trace

Flush

**public void flush()**

**Description copied from interface:** TraceWriter

Forces output of any messages that have been printed using the println method

Specified by:

flush in interface TraceWriter

**close**

```
public void close()
```

**Description copied from interface:** TraceWriter

Releases any resources associated by this TraceWriter.

Specified by:

close in interface TraceWriter

**getEnabled**

```
public boolean getEnabled()
```

Returns true if any one of the underlying TraceWriter is enabled, else returns false.

Specified by:

getEnabled in interface TraceWriter

Returns:

True if this TraceWriter is enabled, false if not.

**getName**

```
public java.lang.String getName()
```

Specified by:

```
getName in interface TraceWriter
```

Returns:

The name of this TraceWriter.

### **getDescription**

```
public java.lang.String getDescription()
```

Specified by:

```
getDescription in interface TraceWriter
```

Returns:

A short description of this TraceWriter.

### **setTraceLevels**

```
public void setTraceLevels(int[]levels)
```

The TraceWriterManager does nothing for this method .

Specified by:

```
setTraceLevels in interface TraceWriter
```

Parameters:

Levels - Array of trace levels.

See Also:

Trace

### **getTraceLevels**

```
public int[] getTraceLevels()
```

The TraceWriterManager returns a null, as the traceLevel is maintained at the individual TraceWriter .

Specified by:

```
getTraceLevels in interface TraceWriter
```

Returns:

null

## CHAPTER 7

# Cisco Unified JTAPI Examples

This chapter provides the source code for `makecall`, the Cisco Unified JTAPI program that is used to test the JTAPI installation. The `makecall` program comprises a series of programs that were written in Java by using the Cisco Unified JTAPI implementation.

For instructions on how to invoke `makecall`, see [Running `makecall`, on page 757](#).

The Cisco Unified JTAPI Test tool can also be used to review message examples and test JTAPI features and functions. For details, refer <http://developer.cisco.com/web/jtapi/docs>.

## Running makecall

To Invoke makecall on the client workstation, from the Windows NT command line, navigate to the **makecall** directory where JTAPI Tools directory was installed and execute the following command:

```
jview makecall <server name> <login> <password> 1000 <device 1> <device2>
```

`<server name>` specifies the hostname or IP address of your Cisco Unified Communications Manager.

`<device1>` and `<device2>` are directory numbers of IP phones. Make sure that the phones are part of the associated devices of a given user as administered in the Cisco Unified Communications Manager's directory administration.

`<login>` and `<password>` apply similarly as administered in the directory.

This will test that you have installed and configured everything correctly. The application will make calls between the two devices with an action delay of 1000 msec until terminated.

## Agent Greeting

The basic Agent Greeting use cases assume a common setup.

In the real-world scenario, an external customer calls a number and is routed through an IVR until the call is eventually offered to an agent.

IP Phones:

- Customer (1000)
- Agents (2000, 2001, 2002)
- IVRs (5000, 5001)

**Scenario One**

Agent Greeting Start Success

| Action                              | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Call information / Notes                                                                                                       |

| 2. The application gets the TerminalConnection for 2000 on GC1 and invokes addMediaStream("5000", "2000"). |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | No BIB call is created. JTAPI throws a ResourceUnavailableException with text as "Unable to allocate built in bridge resource".<br>The call continues as normal. |
| 3. The agent finishes the conversation and ends the call.                                                  | GC1 - TermConnDroppedEv (Term of 2000)<br>GC1 - CallCtlTermConnDroppedEv (Term of 2000)<br>GC1 - ConnDisconnectedEvent (2000)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | The primary call is cleaned up.                                                                                                                                  |

## API for Exposing Built-in-Bridge Status

Phone TermA, CTI port TermB, and RoutePoint TermC are in application's control list.

**Use Case One**

BIB is disabled on service parameters and device page of TermA.

| Action                         | Result                      | Call information |
|--------------------------------|-----------------------------|------------------|
| TermA.isBuiltInBridgeEnabled() | False                       |                  |
| TermB.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |
| TermC.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |

**Use Case Two**

BIB is disabled on service parameters page and enabled on device page of TermA..

| Action                         | Result                      | Call information |
|--------------------------------|-----------------------------|------------------|
| TermA.isBuiltInBridgeEnabled() | True                        |                  |
| TermB.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |
| TermC.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |

**Use Case Three**

BIB is enabled on service parameters page and disabled on device page of TermA.

| Action                         | Result                      | Call information |
|--------------------------------|-----------------------------|------------------|
| TermA.isBuiltInBridgeEnabled() | False                       |                  |
| TermB.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |
| TermC.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |

**Use Case Four**

BIB is enabled on service parameters page and set to default on device page of TermA.

| Action                         | Result                      | Call information |
|--------------------------------|-----------------------------|------------------|
| TermA.isBuiltInBridgeEnabled() | True                        |                  |
| TermB.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |
| TermC.isBuiltInBridgeEnabled() | MethodNotSupportedException |                  |

**Use Case Five**

Phone TermA is not registered. BIB is enabled on device page of TermA.

| Action                                      | Result                      | Call information |
|---------------------------------------------|-----------------------------|------------------|
| TermA.isBuiltInBridgeEnabled()              | InvalidStateException       |                  |
| Add observers and register TermB and TermC. |                             |                  |
| TermB.isBuiltInBridgeEnabled()              | MethodNotSupportedException |                  |
| TermC.isBuiltInBridgeEnabled()              | MethodNotSupportedException |                  |

## Backward Compatibility Enhancements

This feature is not expected to change the performance or scalability of Cisco Unified Communications Manager JTAPI. There is no change in the number of events between JTAPI and CTI. For features involving GCID changes this feature introduces one extra event which should not cause any performance issues.

In all cases events listed below are delivered to call observers when only one party is in control list. TERMA indicates terminal of A.

### Scenario One

A calls B, B transfers the call to C. GC1 is the call between A and B, GC2 is the consult call between B and C. Similar events are delivered for Conference and other features.

| Action                                                 | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Scenario Two**

A calls B, call = GC1. B parks the call at 99999. C unparks the call using call GC2.

| Action                                                                                         | Events |

**Scenario Three**

A calls B, B has forward no answer to C. B does not answer and call is offered to C.

| Action                                  | Events |
|-----------------------------------------|--------|
| Events delivered to call observer on A. |        |

## Barge and Privacy

The following diagrams illustrate the message flows for Barge and Privacy.

# Barge

Scenario: 2005 is Sharedline appearing on terminal SEP003094C25AFF (T1) and Terminal SEP003094C2A0B0(T2). 2000 makes calls to 2005, 2005-T1 answers the Call. Now T2 Barges into the Call.

# CBarge

Scenario: 3005 is Shared line appearing on terminal SEP003094C25AFF (T1) and Terminal SEP003094C2A0B0(T2). 3000 makes calls to 3005, 3005-T1 answers the Call. Now T2 CBarges into the Call.

# Privacy

# Call Control Discovery

## Scenario 1: A Calls 1000 in Other Cluster (SAF ICT)

| Action                                                                                                                               | Result                                                                                                                                                           | Call info                                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|

## Call Recording for SIP or TLS Authenticated calls

### Scenario One

Recording behavior for an authenticated Phone when Service Parameter **Authenticated Phone Recording** set to **Do not Allow Recording**.

B is an Authenticated Phone having selective recording configured and Recording Profile assigned to it. Caller A calls B. B answers the call.

| Action                     | Events                                 | Call information                                                         |
|----------------------------|----------------------------------------|--------------------------------------------------------------------------|
| termConnB.startRecording() | Recording fails with PlatformException | PlatformException.getErrorCode=<br>Code=ERR_SECURITY_CAPABILITY_MISMATCH |

### Scenario Two

Recording behavior for an authenticated Phone when Service Parameter **Authenticated Phone Recording** set to **Allow Recording**.

B is an Authenticated Phone having selective recording configured and Recording Profile assigned to it. Caller A calls B. B answers the call.

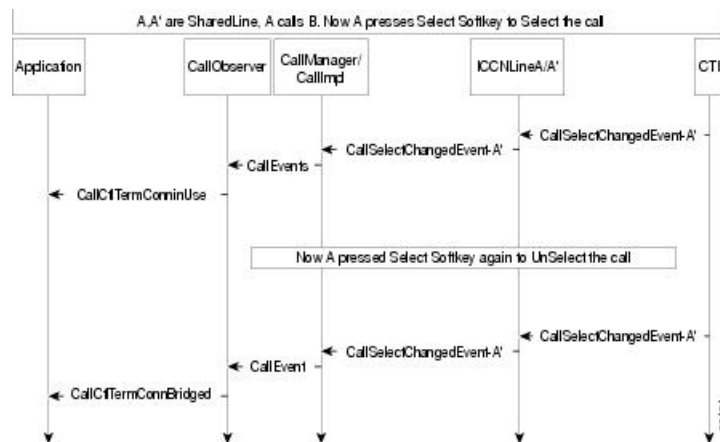

| Action                     | Events                                                                                                                                                                                                                                                                                                                                   | Call information                   |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| termConnB.startRecording() | <p>Along with the regular events for call answer, the following events will also be delivered to the call observer:</p> <p>CiscoTermConnRecordingStartEv Cause: CAUSE_NORMAL</p> <p>CiscoTermConnRecordingTargetInfoEv</p> <p>CiscoTermConnRecordingEndEv Cause: CAUSE_NORMAL</p> <p>CallCtlTermConnDroppedEv TA Cause: CAUSE_NORMAL</p> | <p>Calling: A</p> <p>Called: B</p> |

B is an Authenticated Phone having auto recording configured and Recording Profile assigned to it. Caller A calls B. B answers the call.

| Action         | Events                                                                                                                                                                                                                                                                                                                                   | Call Information                   |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| When B answers | <p>Along with the regular events for call answer, the following events will also be delivered to the call observer:</p> <p>CiscoTermConnRecordingStartEv Cause: CAUSE_NORMAL</p> <p>CiscoTermConnRecordingTargetInfoEv</p> <p>CiscoTermConnRecordingEndEv Cause: CAUSE_NORMAL</p> <p>CallCtlTermConnDroppedEv TA Cause: CAUSE_NORMAL</p> | <p>Calling: A</p> <p>Called: B</p> |

## CallSelect and UnSelect

The following diagram illustrates the message flows for CallSelect and UnSelect.

# Cius Persistency

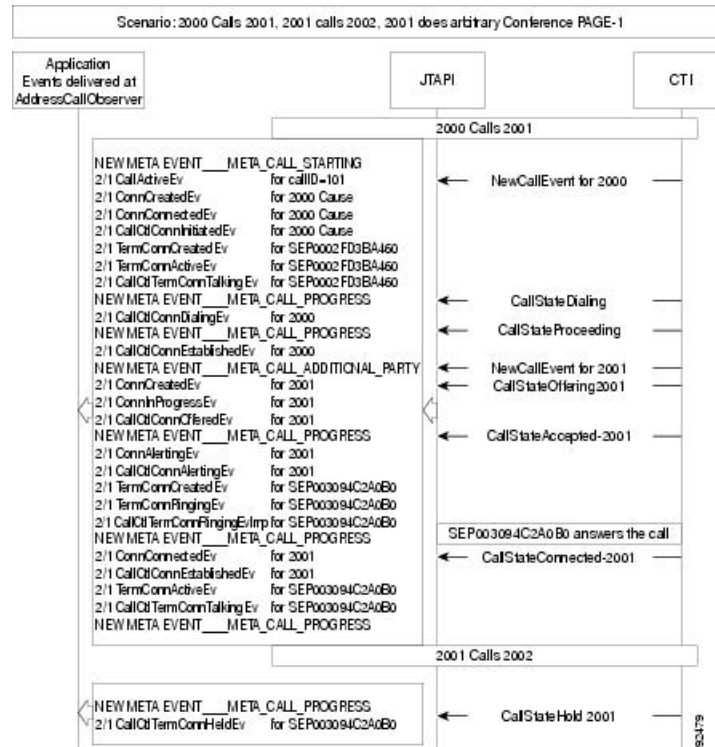

## Use Cases for Cius Persistency

| Usecase                                                                                                           | Events on Provider observer               | Info                                                                                                                                                                                                                                               |

# Conference and Join

The following diagrams illustrate the message flows for Conference and Join.

## Join/Arbitrary Conference

### Join/Arbitrary Conference—Page 2

## Consult Conference

The message flow for Consult Conference acts the same as the flow for Arbitrary Conference.

## Join Across Lines with Enhancements

The message flows for Join Across Lines with Enhancements are described in following tables. A, C, D, E and F are addresses on different terminals. B1 and B2 are addresses on the same terminal, TermB.

| Action                                                                                                                   | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## CTI Manager Redundancy Handling with Least Priority CTIManager Configured

Identify a CTIManager as least priority:

Application can mark one of the CTIManagers in the initial CTIManager redundancy group or configure a new one (not part of the initial group) by invoking setLeastPriorityCtiServer().

# CTI Manager Redundancy Handling with Least Priority CTI Server Set

## Scenario 1: Set least priority without specifying fallback Initiation time

1. Start application and set a CTIManager as least priority. Assume CTIManager redundancy list is CT1,CTI2,CTI3.
2. Application loses connectivity to CTI1.
3. Application loses connectivity to CTI3.
4. CTI1 is reachable now.
5. Fallback is started 5 min from now if a CTI server is reachable post it.
6. Post 5 min, CTI1 is still reachable.

| Action                                                             | Events                                                                          |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Application invokes CiscoProvider.setLeastPriorityCtiServer(CTI2). |                                                                                 |
| Application connects to CTI3.                                      |                                                                                 |
| Application connects to CTI2.                                      | CiscoProvConnToLeastPriorCtiServerEv                                            |
| JTAPI is able to identify CTI1 reachability.                       | CiscoProvPrimNwReachableEv                                                      |
| JTAPI initiates application fallback to CTI1                       | Once connected to CTI1, JTAPI delivers CiscoProvFallbackToPrimNwCompltdEv event |

## Scenario 2: Application initiates a forced fallback

1. Start application and set a CTIManager as least priority. Assume CTIManager redundancy list is CT1,CTI2,CTI3.
2. Application loses connectivity to CTI1.
3. Application loses connectivity to CTI3.
4. CTI1 is reachable now.
5. Application monitors if CTI2 is reachable now.

| Action                                                                                                           | Events | Result |
|------------------------------------------------------------------------------------------------------------------|--------|--------|
| Application invokes CiscoProvider.setLeastPriorityCtiServer(CTI2,600) where 600 is the fallback initiation time. |        |        |
| Application connects to CTI3.                                                                                    |        |        |

| Action                                                          | Events                                                                                                                                 | Result                                                                                                                                    |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|

## CTI Remote Device

### Use Cases

- Group 1: Get/Add/Remove/Update on Remote Destinations
- Group 2: CTIRD Incoming/Outgoing/Disconnect/Redirect/Hold/Resume and shared-line call scenarios)
- Group 3 (CUCSF registration and unregistration, for Normal SIP mode <-> Extend mode, and terminal switching scenarios
- Group 4: Set/Reset Active Remote Destination scenarios
- Group 5: CTIRD Transfer/Conference/Multiple-Calls call scenarios
- Group 6: CTIRD URI-Dialing basic Incoming & Outgoing DVO call scenarios

## CTI Remote Device Use Cases Group 1

### Scenario 1-1 (Expose All RDs Information on a CTI Remote Device to Application)

User1 has "CTI Remote Device A" in the control list. User invokes  
CiscoRemoteTerminal.getAllRemoteDestinations() on terminal A.

| Action                                             | Events          | Call info |
|----------------------------------------------------|-----------------|-----------|
| User1 opens Provider and adds a provider observer. | ProvInServiceEv |           |

| Action                                                                 | Events | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| User1 invokes CiscoRemoteTerminal.getAllRemoteDestinations() on TermA. |        | <pre>TermA.getAllRemoteDestinations() = CiscoRemoteDestinationInfo[2]. CiscoRemoteDestinationInfo[0].getRemoteDestinationName() = "RD1-A" CiscoRemoteDestinationInfo[0].getRemoteDestinationNumber() = "4081001111" CiscoRemoteDestinationInfo[0].getIsActiveRD() = true CiscoRemoteDestinationInfo[1].getRemoteDestinationName() = "RD2-A" CiscoRemoteDestinationInfo[1].getRemoteDestinationNumber() = "4081002222" CiscoRemoteDestinationInfo[1].getIsActiveRD() = false</pre> |

**Use Cases Group 1: Get/Add/Remove/Update on Remote Destinations**

Pre-conditions on Use Cases group 1 below with default jtapi.ini settings, unless specified explicitly:

- Provider is IN\_SERVICE state.
- Device A (CTI Remote Device - Name: "CTIRD-A", Line A (DN: 1000))
- Remote Destination 1 (Name: "RD1-A", Number: "4081001111", Active RD: true)
- Remote Destination 2 (Name: "RD2-A", Number: "4081002222", Active RD: false)
- Device B (IP Phone - Name: "SEP000DED47D023", Line B (DN: 2000))
- Device C (CTI Remote Device - Name: "CTIRD-C", Line C (DN: 3000))
- No Remote Destination configured.

**Scenario 1-2 (Expose Active RDs Information on a CTI Remote Device to Application)**

User1 has "CTI Remote Device A" in the control list. User invokes CiscoRemoteTerminal.getActiveRemoteDestinations() on terminal A.

| Action                                                                    | Events          | Call info                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| User1 opens Provider and adds a provider observer.                        | ProvInServiceEv |                                                                                                                                                                                                                                                                                   |
| User1 invokes CiscoRemoteTerminal.getActiveRemoteDestinations() on TermA. |                 | <pre>TermA.getActiveRemoteDestinations() = CiscoRemoteDestinationInfo[1]. CiscoRemoteDestinationInfo[0].getRemoteDestinationName() = "RD1-A" CiscoRemoteDestinationInfo[0].getRemoteDestinationNumber() = "4081001111" CiscoRemoteDestinationInfo[0].getIsActiveRD() = true</pre> |

**Scenario 1-3 (Fetch RD Information on a CTI Remote Device That Has No RD Configured)**

User1 has "CTI Remote Device C" in the control list. User invokes CiscoRemoteTerminal.getAllRemoteDestinations() on terminal C.

| Action                                                                 | Events          | Call info                                |
|------------------------------------------------------------------------|-----------------|------------------------------------------|
| User1 opens Provider and adds a provider observer.                     | ProvInServiceEv |                                          |
| User1 invokes CiscoRemoteTerminal.getAllRemoteDestinations() on TermC. |                 | TermC.getAllRemoteDestinations() = null. |

**Scenario 1-4 (Fetch RD Information on a 'Non-CTI Remote Device')**

User1 has "Device B" IP Phone in the control list. User invokes CiscoRemoteTerminal.getAllRemoteDestinations() on terminal B.

| Action                                                                 | Events          | Call info                                |
|------------------------------------------------------------------------|-----------------|------------------------------------------|
| User1 opens Provider and adds a provider observer.                     | ProvInServiceEv |                                          |
| User1 invokes CiscoRemoteTerminal.getAllRemoteDestinations() on TermB. |                 | TermB.getAllRemoteDestinations() = null. |

**Scenario 1-5 (Fetch Active RD Information on a CTI Remote Device That Has No Active RD Configured)**

User1 has "CTI Remote Device C" in the control list. User invokes CiscoRemoteTerminal.getActiveRemoteDestinations() on terminal C.

| Action                                                                 | Events          | Call info                                   |
|------------------------------------------------------------------------|-----------------|---------------------------------------------|
| User1 opens Provider and adds a provider observer.                     | ProvInServiceEv |                                             |
| User1 invokes CiscoRemoteTerminal.getAllRemoteDestinations() on TermC. |                 | TermC.getActiveRemoteDestinations() = null. |

**Scenario 1-6 (Set a Non-Active RD as a New Active RD on a 'CTI Remote Device', Where There Is Already an Existing Active RD for This Device)**

User1 has "CTI Remote Device A" in the control list. User invokes CiscoRemoteTerminal.setActiveRemoteDestination("4081002222", true) on terminal A.

| Action                                                                                     | Events                                      | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| User1 opens Provider and adds a provider observer.                                         | ProvInServiceEv                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| User1 invokes CiscoRemoteTerminal.setActiveRemoteDestination("4081002222", true) on TermA. | CiscoProvTerminalRemoteDestinationChangedEv | CiscoProvTerminalRemoteDestinationChangedEv.<br>getRemoteDestinations() = CiscoRemoteDestinationInfo[2].<br>CiscoRemoteDestinationInfo[0].getRemoteDestinationName() = "RD1-A"<br>CiscoRemoteDestinationInfo[0].getRemoteDestinationNumber() = "4081001111"<br>CiscoRemoteDestinationInfo[0].getIsActiveRD() = false<br>CiscoRemoteDestinationInfo[1].getRemoteDestinationName() = "RD2-A"<br>CiscoRemoteDestinationInfo[1].getRemoteDestinationNumber() = "4081002222"<br>CiscoRemoteDestinationInfo[1].getIsActiveRD() = false |
|                                                                                            | CiscoProvTerminalRemoteDestinationChangedEv | CiscoProvTerminalRemoteDestinationChangedEv.<br>getRemoteDestinations() = CiscoRemoteDestinationInfo[2].<br>CiscoRemoteDestinationInfo[0].getRemoteDestinationName() = "RD1-A"<br>CiscoRemoteDestinationInfo[0].getRemoteDestinationNumber() = "4081001111"<br>CiscoRemoteDestinationInfo[0].getIsActiveRD() = false<br>CiscoRemoteDestinationInfo[1].getRemoteDestinationName() = "RD2-A"<br>CiscoRemoteDestinationInfo[1].getRemoteDestinationNumber() = "4081002222"<br>CiscoRemoteDestinationInfo[1].getIsActiveRD() = true  |

**Scenario 1-7 (Add a New Non-Active RD on a 'CTI Remote Device')**

User1 has "CTI Remote Device A" in the control list. User invokes addRemoteDestination("RD3-A", "4081003333", false) on terminal A.

| Action                                             | Events          | Call info |
|----------------------------------------------------|-----------------|-----------|
| User1 opens Provider and adds a provider observer. | ProvInServiceEv |           |

| Action                                                                                          | Events                                      | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Scenario 1-11 (Remove All RD(s) From a 'CTI Remote Device')**

User1 has "CTI Remote Device A" in the control list. User invokes removeAllRemoteDestinations() on terminal A.

**Note** JTAPI will loop through the terminal/device's existing remote destinations one by one, so the total number of CiscoProvTerminalRemoteDestinationChangedEv sent to an application should be the same number of available remote destinations being removed. And the order and content of each event can vary, depending on how each remote destination is stored in JTAPI's local cache RD list.

| Action                                                                    | Events                                      | Call info                                                                                                                                                                                                                                                                                                        |

| User1 invokes CiscoRemoteTerminal.setActiveRemoteDestination("4081001111", false) on TermA. | CiscoProvTerminalRemoteDestinationChangedEv | CiscoProvTerminalRemoteDestinationChangedEv.getRemoteDestinations() = CiscoRemoteDestinationInfo[3].<br>CiscoRemoteDestinationInfo[0].getRemoteDestinationName() = "RD1-A"<br>CiscoRemoteDestinationInfo[0].getRemoteDestinationNumber() = "4081001111"<br>CiscoRemoteDestinationInfo[0].getIsActiveRD() = false<br>CiscoRemoteDestinationInfo[1].getRemoteDestinationName() = "RD2-A"<br>CiscoRemoteDestinationInfo[1].getRemoteDestinationNumber() = "4081002222"<br>CiscoRemoteDestinationInfo[1].getIsActiveRD() = false<br>CiscoRemoteDestinationInfo[2].getRemoteDestinationName() = "RD3-A"<br>CiscoRemoteDestinationInfo[2].getRemoteDestinationNumber() = "4081003333"<br>CiscoRemoteDestinationInfo[2].getIsActiveRD() = false |

**Scenario 1-18 (Remove All RD(s) From a 'CTI Remote Device')**

User1 Has "CTI Remote Device C" in the Control List. User Invokes removeAllRemoteDestinations() on Terminal C.

| Action                                                                    | Events          | Call info5                                                                                                                                                |
|---------------------------------------------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| User1 opens Provider and adds a provider observer.                        | ProvInServiceEv |                                                                                                                                                           |
| User1 invokes CiscoRemoteTerminal.removeAllRemoteDestinations() on TermC. |                 | <b>Note</b> Nothing is removed as there is no RD on this device. JTAPI won't be sending any request to CTI. No CiscoJtapiException will be thrown either. |

**Scenario 1-19 (Remove All 5 RD(s) From a 'CTI Remote Device')**

Explicit Pre-condition: RD1-A: "4081001111", true; RD2-A: "4081002222", false; RD3-A: "4081003333", false; RD4-A: "4081004444", false; RD5-A: "4081005555", false.

User1 has "CTI Remote Device A" in the control list. User invokes removeAllRemoteDestinations() on terminal A.

Note that JTAPI will loop through the terminal/device's existing remote destinations one by one, so the total number of CiscoProvTerminalRemoteDestinationChangedEv sent to an application should be the same number

of available remote destinations being removed. And the order and content of each event can vary, depending on how each remote destination is stored in JTAPI's local cache RD list.

Also note currently there is no checking in JTAPI to limit only up to 5 RDs per CTI Remote Device. If application tries to add a new RD to an existing CTI Remote Device that already has 5 RDs, JTAPI will simply send the add request to CTI and let it decide on pass/fail.

| Action                                                                    | Events                                      | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## CTI Remote Device Use Cases Group 2

### Use Cases Group 2: CTIRD Incoming/Outgoing/Disconnect/Redirect/Hold/Resume and Shared-Line Call Scenarios

Pre-conditions on Use Cases group 2 below with default jtapi.ini settings, unless specified explicitly. Note that the CTI Ports have Auto-Accept enabled:

- Provider is IN\_SERVICE state.
- Device A (CTI Remote Device - Name: "irvCTIRD1", Line A (DN: 8881000))
- Remote Destination 1 (Name: "IRVOffice", Number: "919498231202", Active RD: true)
- Device B (CTI Port - Name: "irvCTIPort1", Line B (DN: 8881000))
- Device C (CTI Port - Name: "irvCTIPort6", Line C (DN: 8886000))
- Device D (CTI Port - Name: "irvCTIPort7", Line C (DN: 8887000))
- Device E (CTI Remote Device - Name: "irvCTIRD2", Line E (DN: 8889000))
- Remote Destination 1 (Name: "IRVCell1", Number: "916267829523", Active RD: true)
- Device F (CTI Remote Device - Name: "irvCTIRD3", Line E (DN: 8889001))
- Remote Destination 1 (Name: "IRVCell2", Number: "916267829526", Active RD: true)

#### Scenario 2-1 (Incoming Call From CTI Port to CTI Remote Device)

C calls E, Application is observing both C and E on addresses and terminals. GC1 is the GCID of the call.

| Action                                                                  | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Call info                                                                                                                                                                                                                              |

## CTI Remote Device Use Cases Group 3

**Use Cases Group 3 (CUCSF Registration and Unregistration, for Normal SIP Mode <-> Extend Mode, and Terminal Switching Scenarios)**

Pre-conditions on Use Cases group 3 below with default jtapi.ini settings, unless specified explicitly:

- Provider is IN\_SERVICE state.
- Device A (CUCSF - Name: "irvCSF1", Line A (DN: 7771000))
- Remote Destination 1 (Name: "IRVCell", Number: "916267829523", Active RD: true)
- Scenario 3-1 (Registration of CUCSF in between Extend mode and SIP mode).:

Device A is registered in normal SIP mode when Webex with Jabber client is running and configured this device as its associated phone. User1 open provider and add observers on this device to bring it in service. Now exit Webex to unregister it from SIP, and then User1 calls `CiscoTerminal.register()` to register it to Extend mode from JTAPI, then add observers back to bring it in service. Now User1 unregister it from Extend mode in JTAPI by calling `CiscoRemoteTerminal.unregister()`. Now open Webex again to register this device back to SIP mode, and add observers back to bring it in service.

## CTI Remote Device Use Cases Group 4

### Use Cases Group 4 (Set/Reset Active Remote Destination Scenarios)

Pre-conditions on Use Cases group 4 below with default jtapi.ini settings, unless specified explicitly:

- Provider is IN\_SERVICE state. Single node.
- Device A (CTI Remote Device - Name: "irvCTIRD2", Line A (DN: 8881000))
- Remote Destination 1 (Name: "IRVCell1", Number: "916267829523", Active RD: false)
- Scenario 4-1 (User1 opens provider P1, set RD1 as active. Now User1 opens another provider P2, and set same RD1 as active again. Now stop CTI Manager service in this single node, the active RD would be clear out. Now restart CTI Manager, JTAPI will do a provider retry, and upon successfully connection, it will automatically reset the same RD1 as active again seamlessly.):

### Scenario 5-1 (Direct Transfer on CTI Remote Device to CTI Port)

D calls A with GC1 as GCID of call; A calls B with GC2 as GCID of call. Set A as transfer controller, and then transfer call from GC2 to GC1. Application is observing all A, B, D.

**Scenario 5-2 (Conference Call on CTI Remote Device and CTI Port with Another CTI Remote Device)**

D calls A with GC1 as GCID of call; A calls E with GC2 as GCID of call. Set A as conference controller, and then conference/join call from GC2 to GC1. Application is observing all A, D, E.

**Scenario 5-3 (Multiple Calls on CTI Remote Device)**

D calls A with GC1 as GCID of call; B calls A with GC2 as GCID of call. Application is observing all A, B, D.

## CTI Remote Device Use Cases Group 6

### Use Cases Group 6 (CTIRD URI-Dialing Basic Incoming and Outgoing DVO Call Scenarios)

Pre-conditions on Use Cases group 6 below with default jtapi.ini settings, unless specified explicitly (Note: The CTI Ports have Auto-Accept enabled):

- Provider is IN\_SERVICE state.
- Device A (CTI Remote Device - Name: "irvCTIRD3", Line A (DN: 8889001, Directory URIs: "8889001A@cisco.com"))
- Remote Destination 1 (Name: "IRVCell1", Number: "916267829523", Active RD: true)
- Device B (CTI Port - Name: "irvCTIPort2", Line B (DN: 8882000, Directory URIs: "8882000A@cisco.com"))

### Scenario 6-1 (Basic Incoming Call From CTI Port to CTI Remote Device Via URI)

B calls A with GC1 as GCID of call. Application is observing both A and B.

| Action                                                                            | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Call info                                                                                                                                                                                                                              |

## CTI Video Support

Use cases related to CTI Video Support feature are mentioned below:

### Scenario 1:

Phone A is video capable, telepresence capable, with 1 screen and a camera, and in registered state. User1 has phone A in the control list. User invokes `CiscoTerminal.getCiscoMultiMediaCapabilityInfo().getVideoCapability()` before opening the device.

| Action                                                                                                       | Events          | Call info                                                                                                 |
|--------------------------------------------------------------------------------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------|
| User1 Opens Provider and adds a provider observer                                                            | ProvInServiceEv |                                                                                                           |
| User1 invokes <code>CiscoTerminal.i.getCiscoMultiMediaCapabilityInfo().getVideoCapability()</code> on termA  |                 | <code>termA.getCiscoMultiMediaCapabilityInfo().getVideoCapability() = VIDEO_ENABLED</code>                |
| User1 invokes <code>CiscoTerminal.i.getCiscoMultiMediaCapabilityInfo().getTelepresenceInfo()</code> on termA |                 | <code>termA.getCiscoMultiMediaCapabilityInfo().getTelepresenceInfo() = TELEPRESENCEINTEROP_ENABLED</code> |

| Action                                                                                              | Events | Call info                                                           |
|-----------------------------------------------------------------------------------------------------|--------|---------------------------------------------------------------------|
| User1 invokes CiscoTerminal. i<br>getCiscoMultiMediaCapabilityInfo().<br>getScreenCount () on termA |        | termA. getCiscoMultiMediaCapabilityInfo(). getScreenCount ()<br>= 1 |

**Scenario 2**

Phone A is not video capable, not telepresence capable with 0 screens. User1 has phone A in the control list. The user invokes CiscoTerminal.getCiscoMultiMediaCapabilityInfo().getVideoCapability() before opening device

| Action                                                                                                   | Events          | Call info                                                                                       |
|----------------------------------------------------------------------------------------------------------|-----------------|-------------------------------------------------------------------------------------------------|
| User1 Opens Provider and adds a provider<br>observer                                                     | ProvInServiceEv |                                                                                                 |
| User1 invokes CiscoTerminal.<br>getCiscoMultiMediaCapabilityInfo().<br>getVideoCapability() on termA     |                 | termA. getCiscoMultiMediaCapabilityInfo(). getVideoCapability()<br>= NONE                       |
| User1 invokes CiscoTerminal. i<br>getCiscoMultiMediaCapabilityInfo().<br>getTelepresenceInfo () on termA |                 | termA. getCiscoMultiMediaCapabilityInfo(). getTelepresenceInfo<br>() = TELEPRESENCEINTEROP_NONE |

130189

## Do Not Disturb

Configuration: Application is observing terminal A and terminal B.

### Scenario One

Application adds Terminal observer to terminal A using `Terminal.addObserver()`. Filter is enabled via `setDNDChangedEvFilter`. DND is enabled on the terminal. Application invokes `getDNDStatus()` from `CiscoTerminal`.

| Action                                                                                                                                                                                                                                                 | Events                                                                                                                                                                                             | Call info |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| <p>Application adds terminal observer to terminal A. Filter is enabled via setDNDChangedEvFilter() in CiscoTermEvFilter. DND is enabled on the terminal through phone or admin page.</p> <p>Application invokes getDNDStatus() from CiscoTerminal.</p> | <p>NEW META EVENT _____</p> <p>META_CALL_STARTING</p> <p>CiscoTermDNDStatusChangedEv A</p> <p>Cause: CAUSE_NORMAL for DND Status: true</p> <p>DND status = true is returned to the application</p> | N.A       |

**Scenario Two**

Application enables filter to receive events. Application adds Terminal observer to terminal A using Terminal.addObserver(). DND is enabled on the terminal. Application invokes getDNDStatus() from CiscoTerminal.

| Action                                                                                                                                                                                                                          | Events                                                                                                                                                                                      | Call info |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| <p>Application enables filter to receive events. Application adds terminal observer to terminal A. DND is enabled on the device through phone or admin pages.</p> <p>Application invokes getDNDStatus() from CiscoTerminal.</p> | <p>NEW META</p> <p>EVENT _____ META_CALL_STARTING</p> <p>CiscoTermDNDStatusChangedEv A Cause: CAUSE_NORMAL for DND Status: true</p> <p>DND status = true is returned to the application</p> | N.A       |

**Scenario Three**

Application adds Terminal observer to terminal A using Terminal.addObserver(). Filter is disabled via setDNDChangedEvFilter() in CiscoTermEvFilter. Application invokes getDNDStatus() from CiscoTerminal.

| Action                                                                                                                                                                                                                   | Events                                                              | Call info |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|-----------|
| <p>Application adds Terminal observer to terminal A using Terminal.addObserver(). Filter is disabled via setDNDChangedEvFilter() in CiscoTermEvFilter.</p> <p>Application invokes getDNDStatus() from CiscoTerminal.</p> | <p>CiscoTermDNDStatusChangedEv is not delivered to application.</p> | N.A       |

**Scenario Four**

Application does not add Terminal observer to terminal. Application invokes getDNDStatus() from CiscoTerminal.

| Action                                                                                                                | Events                                 | Call info |
|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------|-----------|
| <p>Application does not add Terminal observer to terminal. Application invokes getDNDStatus() from CiscoTerminal.</p> | <p>InvalidStateException is thrown</p> | N.A       |

**Scenario Five**

Application does not enable the filter to receive events. Application adds Terminal observer to terminal A. DND status is set to true through the phone or admin pages. Application now enables the filter to receive events. Application invokes getDNDStatus() from CiscoTerminal.

| Action                                                                                                                                                                                                                                                                                    | Events                                                                                                                                                                                                                               | Call info |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| Application does not enable the filter to receive events. Application adds Terminal observer to terminal A. DND status is set to true through the phone or admin pages.<br>Application now enables the filter to receive events<br>Application invokes getDNDStatus() from CiscoTerminal. | CiscoTermDNDStatusChangedEv is not delivered to application.<br>NEW META EVENT _____<br>META_CALL_STARTING<br>CiscoTermDNDStatusChangedEv A Cause: CAUSE_NORMAL for DND Status: true<br>DND status = true is returned to application | N.A       |

**Scenario Six**

Application sets DND status to false by invoking the setDNDStatus() interface on CiscoTerminal.

| Action                                                 | Events                                                                                                                   | Call info |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|-----------|
| Application invokes setDNDStatus() from CiscoTerminal. | NEW META EVENT _____<br>META_CALL_STARTING<br>CiscoTermDNDStatusChangedEv A<br>Cause: CAUSE_NORMAL for DND Status: false | N.A       |

**Scenario Seven**

Application 1 and Application 2 are observing terminal a, and both the applications have enabled the filter to receive events. Application 1 sets DND status to false on Terminal A. Application 2 is observing Terminal A.

| Action                                                 | Events                                                                                                                   | Call info |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|-----------|
| Application invokes setDNDStatus() from CiscoTerminal. | NEW META EVENT _____<br>META_CALL_STARTING<br>CiscoTermDNDStatusChangedEv A<br>Cause: CAUSE_NORMAL for DND Status: false | N.A       |

**Scenario Eight**

DND Type is RingerOff and CFNA is not set. Terminal B calls Terminal A. Call is presented to A and call is not answered.

| Action                                                                                       | Events                                                                                                           | Call info |
|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|-----------|
| Application invokes redirect() API with feature priority set to 3 from CiscoCall.            | Call is presented to the device, irrespective of the DND settings on the device. CER call overrides DND setting. | N.A       |
| Application invokes selectRoute() API with feature priority set to 3 from CiscoRouteSession. | Call is presented to the device, irrespective of the DND settings on the device. CER call overrides DND setting. | N.A       |

### Scenario Nine

| Action                                                                                                                   | Events                              | Call info |
|--------------------------------------------------------------------------------------------------------------------------|-------------------------------------|-----------|
| DND Type is RingerOff and CFNA is not set. Terminal B calls Terminal A .Call is presented to A and call is not answered. | ConnFailedEv Cause: CAUSE_NO ANSWER | N.A       |

### Scenario Ten

DND Type is CallReject and CFB is not set. Terminal B calls Terminal A. Call is not presented to A.

| Action                                                                                             | Events                              | Call info |
|----------------------------------------------------------------------------------------------------|-------------------------------------|-----------|
| DND Type is CallReject and CFB is not set. Terminal B calls Terminal A. Call is not presented to A | ConnFailedEv Cause: CAUSE_USER BUSY | N.A       |

### Scenario Eleven

DND is enabled on the terminal A. Terminal A comes IN\_SERVICE. Application invokes getDNDStatus() on CiscoTerm in ServiceEv.

| Action                                                         | Events                                                           | Call info |
|----------------------------------------------------------------|------------------------------------------------------------------|-----------|
| DND is enabled on the terminal A. Terminal A comes IN_SERVICE. | CiscoTermInServiceEv<br>Cause: CAUSE_NORMAL<br>DND Status = true | N.A       |

### Scenario Twelve

DND is enabled on terminal A. Terminal A comes IN\_SERVICE. Application invokes setDNDStatus(). DB failure happens after the setDNDStatus() request is sent.

| Action                                                                                                                                                | Events                                                                                                                        | Call info |
|-------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|-----------|
| DND is enabled on the terminal A. Terminal A comes IN_SERVICE. Application invokes setDNDStatus(). DB failure follows and value is not updated in DB. | PlatformException is thrown “Could not meet post conditions of setDNDStatus()”<br>No CiscoTermDNDStatusChangedEv is received. | N.A       |

**Scenario Thirteen**

DND is enabled on the terminalA. Terminal A comes IN\_SERVICE, DND status is currently true in phone/admin. Application tries to set the same value i.e. invokes setDNDStatus(true).

| Action                                                                                                                                                                             | Events                                                                                                                    | Call info |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|-----------|
| DND is enabled on the terminal A. Terminal A comes IN_SERVICE.DND status is currently true in phone/admin.Application tries to set the same value i.e. invokes setDNDStatus(true). | InvalidStateException is caught: DND status with value true is already set<br>No CiscoTermDNDStatusChangedEv is received. | N.A       |

**DND-R**

**Scenario One**

Application adds Terminal observer to terminal A using Terminal.addObserver (). DND-R is enabled on the terminal B via the Admin page or the Common profile page.

| Action                                                                                                                                                                                        | Events                                                                                                                                                                                                                                                                                            | Call info |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| Application adds terminal observers to terminal A and B. DND-R is enabled on the terminal B through phone or admin page.<br>A issues Call.connect to B with the feature Priority = 1 (Normal) | NEW META EVENT _____<br>META_CALL_STARTING<br>CallActiveEv for callID = GC1 Cause: CAUSE_NEW_CALL<br>ConnCreatedEv for A Cause: CAUSE_NORMAL<br>ConnConnectedEv for A Cause: CAUSE_NORMAL<br>CallCtlConnInitiatedEv for A Cause: CAUSE_NORMAL<br>ConnFailedEv B Cause:.<br>Cause: CAUSE_USERBUSY. | N.A       |

**Scenario Two**

Application adds Terminal observer to terminal A using Terminal.addObserver (). DND-R is enabled on the Terminal B via the Admin page or the Common profile page.

| Action                                                                                                                                                                                                      | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Call info                          |

## Dynamic CTIPort Registration Per Call

The following diagram illustrates the message flows for Dynamic CTIPort Registration per call.

Dynamic Registration for MediaTerminal:  
 In order to set ipAddress and portNo on per call basis for MediaTerminal, application needs to register MediaTerminal as specified below and need to add terminal Observer and callObserver.

90966

# E911 Teleworker

## SelectRoute Method

| Use Case                                       | Events                   | Call info                  |
|------------------------------------------------|--------------------------|----------------------------|
| No changes in use case with selectRoute Method | No changes in the events | No changes in the callinfo |

## Redirect Method

| Use Case                                    | Events                   | Call info                  |
|---------------------------------------------|--------------------------|----------------------------|
| No changes in use case with redirect Method | No changes in the events | No changes in the callinfo |

# Encryption Enhancement

**Table 274: Service Parameter "Require Public Key Encryption" Is Set to "False". Application Is Using a Pre 10.x CiscoJTAPI Version**

| Action                                                    | Result          | Info |
|-----------------------------------------------------------|-----------------|------|
| Application opens a provider and adds a provider observer | ProvInServiceEv |      |

**Table 275: Service Parameter "Require Public Key Encryption" Is Set to "True". Application Is Using a Pre 10.x CiscoJTAPI Version**

| Action                       | Result            | Info                                                                   |
|------------------------------|-------------------|------------------------------------------------------------------------|
| Application opens a provider | PlatformException | getErrorCode() = CiscoJtapiException.<br>INCOMPATIBLE_PROTOCOL_VERSION |

**Table 276: Service Parameter "Require Public Key Encryption" Is Set to "False". Application Is Using a 10.x CiscoJTAPI Version**

| Action                                                    | Result          | Info |
|-----------------------------------------------------------|-----------------|------|
| Application opens a provider and adds a provider observer | ProvInServiceEv |      |

**Table 277: Service Parameter "Require Public Key Encryption" Is Set to "True". Application Is Using a 10.x CiscoJTAPI Version**

| Action                                                    | Result          | Info |
|-----------------------------------------------------------|-----------------|------|
| Application opens a provider and adds a provider observer | ProvInServiceEv |      |

**Table 278: SP Is Set to "True". Application Is Using 10.x CiscoJTAPI Lib. Application Has Provided Pub and Sub Ctmanager IP in the ProviderString**

| Action                                                       | Result           | Info |
|--------------------------------------------------------------|------------------|------|
| Application opens a provider and adds a provider observer    | ProvInServiceEv  |      |
| CTIManager on the server to which app is connected goes down | ProvOutOfService |      |

# End to End Call Tracing

| Actions                                                                                                          | Events                                                                                                                                                                                                                                                                                                                                                | Call info                                                                                                                                                                                                                                                                                                                                  |

## Hunt Log Status for Phone Devices

In the following use cases A, B, C, and D are IP phones where A and B are a part of line group which is configured to hunt pilot HP. A is the first hunt member and it is logged out of the hunt group and B is the second hunt member and it is logged in to the hunt group on hunt pilot. For the following use cases the CiscoTermEvFilter.setHuntLogStatusChangedEvFilter() is set to true.

**Call To Hunt Pilot where device is logged into hunt group**

| <p>There is no action on phone A for the next 10 minutes. So at 6:20 pm, after the idle timer has expired, the terminal enters Deep Sleep mode and unregisters from the Cisco Unified CM.</p> | <p>[Term B] CiscoProvTerminalUnRegisteredEv<br/>                     [Term B] CiscoTermOutOfServiceEv<br/>                     [Addr B] CiscoAddrOutOfServiceEv</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>CiscoProvTerminalUnRegisteredEv.getReason() = CiscoProvTerminalUnRegisteredEv.ENERGYWISE_POWER_SAVE_PLUS<br/>                     CiscoTermOutOfServiceEv.getCause() = CiscoOutOfServiceEv.CAUSE_ENERGYWISE_POWER_SAVE_PLUS<br/>                     CiscoAddrOutOfServiceEv.getCause() = CiscoOutOfServiceEv.CAUSE_ENERGYWISE_POWER_SAVE_PLUS</p> |

# External Call Control

You should assume that all devices in the following use cases are observed, unless explicitly stated otherwise in the use case description.

The first few use cases go through the full event series for the basic call setup. After the first three or four, the use cases leave this part out, as it is standard for most of the use cases. If you do not see the basic call event series at the beginning of a use case, you can assume that it was intended to have happened successfully before the first event in the use case.

The last column in the use cases, that specifies the call info for a various stage of the use case, will initially have the full method invocation to retrieve the call information, for example `CiscoCall.getModifiedCallingParty()`. After the first three or four uses cases, only the method name is specified, such as `.getModifiedCallingParty()`. You can assume that this is to be prefixed with `CiscoCall` unless explicitly stated otherwise, such as for the `CiscoCallChangeEvs`.

## Use Cases for BasicCall

### Basic Call Initiated From JTAPI / Phone

#### Configuration

Phone A, B are in cluster devices.

Procedure:

Application invokes `connect()` at A to call B, or physical phone for A dials the number for B.

| Actions                                                                            | Events                                                                                                                                                                                                                                                                                                                                                                                                            | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

# Use Cases for Calls Going Through Translation Pattern with CEPN Info in Cc Signals

## Basic Call Initiated From JTAPI to the DN with Translation Pattern Configured to Transform Called Party

### Configuration

Phone A, B are in cluster devices.

B has a translation pattern configured where called party get transformed to B1.

Procedure:

Application invokes connect() at A to call B.

| Actions                                           | Events                                                                                                                                                                                                                                                             | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Called Party Redirects a Call Which Has Transformed Calling and Called Parties**

**Configuration**

Phone A, B, C are in cluster devices.

B has a translation pattern configured where both calling and called parties get transformed to A1 and B1 respectively

Procedure:

Application invokes connect() at A to call B. B1 redirects the call in connected state.

| Actions                                                                                                                                                                                                      | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## **Called Party Which Has Transformed Calling and Called Parties Parks the Call and Receives a Park Reminder Call**

### **Configuration**

Phone A, B are in cluster devices. C is a park DN (also in cluster)

B has a translation pattern configured where both calling and called parties get transformed to A1 and B1 respectively

Procedure:

Application invokes connect() at A to call B. B1 answers and then B1 parks the call and after park reversion timer expiry receives the reminder call.

| Actions                                            | Events                           | Call info                                     |

**Calling Party Parks the Call and Receives a Park Reminder Call After a Transformation From Called Party Translation Pattern**

**Configuration**

Phone A, B are in cluster devices. C is a park DN

B has a translation pattern configured where both calling and called parties get transformed to A1 and B1 respectively

Procedure:

Application invokes connect() at A to call B. B1 answers and then A parks the call and after park reversion timer expiry receives the reminder call.

| Actions                                                                                                                                  | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Caller Redirects a Call Which Has Transformed Calling and Called Parties

### Configuration

Phone A, B, C are in cluster devices.

B has a translation pattern configured where both calling and called parties get transformed to A1 and B1 respectively

Procedure:

Application invokes connect() at A to call B. A redirects the call in connected state.

| Actions                                                                                                                                                                                                                      | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Called Party Transfers the Call Which Has Transformed Calling and Called Parties to a DN Which Matches the Translation Pattern with Calling Party Transformation Defined**

**Configuration**

Phone A, B, C are in cluster devices.

B has a translation pattern configured where both calling and called parties get transformed to A1 and B1 respectively

C matches the the translation pattern with calling party transformation to B2

Procedure:

Application invokes connect() at A to call B. B1 consult transfer the call to C.

**Called Party with Transformed Calling and Called Parties Conferences a DN**

**Configuration**

Phone A, B, C are in cluster devices.

B has a translation pattern configured where both calling and called parties get transformed to A1 and B1 respectively

Procedure:

Application invokes connect() at A to call B. B1 consult conference the call to C.

| Actions                                                                                                                                                         | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Called Party with Transformed Calling and Called Parties Conferes a DN Which Matches the Translation Pattern with Calling Party Transformation Defined

#### Configuration

Phone A, B, C are in cluster devices.

B has a translation pattern configured where both calling and called parties get transformed to A1 and B1 respectively

C has a translation pattern configured where calling party gets transformed to B2.

Procedure:

Application invokes connect() at A to call B. B1 consult conference the call to C.

## WildCard Routepoint Interaction (Behavior Change)

### WildCard RoutePoint Redirects a Basic Incoming Call to IPPhone

#### Configuration

Phone A, B are in cluster devices. 4XXX is a wildcard routepoint

Service parameter “Use WildCard pattern in CTI Call Info” is set to true.

Procedure:

Application invokes connect() at A to call 4000. 4XXX redirects the call to B.

| Actions                                                                                                                                                                                                | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Wildcard Routepoint Interaction (Original Behavior)

### Wildcard RoutePoint Redirects a Basic Incoming Call to IPPhone

#### Notes / Caveats

This configuration is not supported. This use case is only intended to show the call flow or events for the above use case with the Use WildCard pattern in CTI Call Info service parameter turned off. Applications should not count on this information to be correct, and to properly support Wildcard Routepoint scenarios, should look to adapting their applications so that they can support the new service parameter being enabled.

An important thing to note is that a connection is created for the dialed DN, 4000. This connection, as well as the connection of 4XXX is not dropped from the call until the redirect happens. This means that if a Wildcard DN is configured on a phone or device, you will see connections for the calling party, 4000, and 4XXX. This basic call will have three connections, which may confuse applications, which might believe it to be a conference call. CiscoCall.isConference() would still return false in this scenario. As stated in previous sections, this extra connection is created in error, and applications should not rely on this connection being there.

#### Configuration

Phone A, B are in cluster devices. 4XXX is a wildcard routepoint

Service parameter “Use WildCard pattern in CTI Call Info” is set to false / OFF.

Procedure:

Application invokes connect() at A to call 4000. 4XXX redirects the call to B.

| Actions                                                                                                                                                   | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## External Call Control Use Cases

### External Call Control on Translation Pattern and CEPM Returns “continue”

#### Configuration

Phone A, B are in cluster devices. B matches the translation pattern BXXX which has calling and called party transformation defined to transform A to A1 and B to B1 and External Call Control is also enabled.

Procedure:

Application invokes connect() at A to call B.

**Result**

Dialed number B matches the translation pattern BXXX which has External Call Control enabled. This takes precedence and CUCM requests CEPM to get routing rule for B.

CEPM returns continue and hence call will be presented to B1 (see use case “Basic Call initiated from JTAPI to the DN with Translation Pattern configured to transform called party” in the [Use Cases for Calls Going Through Translation Pattern with CEPN Info in Cc Signals, on page 929](#) topic).

**External Call Control on Translation Pattern and CEPM Returns “divert”****Configuration**

Phone A, B are in cluster devices. B matches the translation pattern BXXX which has calling and called party transformation defined to transform A to A1 and B to B1 and External Call Control is also enabled.

Procedure:

Application invokes connect() at A to call B.

**Result**

Dialed number B matches the translation pattern BXXX which has External Call Control enabled. This takes precedence and CUCM requests CEPM to get routing rule for B.

CEPM returns divert to C.

**External Call Control on Translation Pattern and CEPM Returns <reject>**

**Configuration**

Phone A, B are in cluster devices. B matches the translation pattern BXXX which has calling and called party transformation defined to transform A to A1 and B to B1 and External Call Control is also enabled.

Procedure:

Application invokes connect() at A to call B.

**Result**

Dialed number B matches the translation pattern BXXX which has External Call Control enabled. This takes precedence and CUCM requests CEPM to get routing rule for B. The routing rule for B says “Reject”<reject> CEPM returns reject.

A receives ConnFailedEvent (cause = CtiCallRejected), ConnDisconnectedEv (cause = normal), CallInvalidEvent (caue = Normal).

**External Call Control on Translation Pattern and CEPM Returns “continue” with Modified Calling and Called Parties**

**Configuration**

Phone A, B are in cluster devices. B matches the translation pattern BXXX which has calling and called party transformation defined to transform A to A1 and B to B1 and External Call Control is also enabled.

Procedure:

Application invokes connect() at A to call B.

**Result**

Dialed number B matches the translation pattern BXXX which has External Call Control enabled. This takes precedence and CUCM requests CEPM to get routing rule for B.

CEPM returns continue with ModifiedCalling = “MA” and ModifiedCalled = “MB”

Call will be extended to “C” (based on description for modified calling and modified called in divertTo routing directive, overrides the calling & called number transformation configured for translation pattern and the call is diverted to C. For details, see [Use Cases for Calls Going Through Translation Pattern with CEPN Info in Cc Signals, on page 929.](#))

Call Events:

CEPM returns divertTo = C, with ModifiedCalling = “MA” and ModifiedCalled = “MB”, resetCallHistory = “resetLastHop”

Call will be extended to “C” (based on description for modified calling and modified called in divertTo routing directive, overrides the calling & called number transformation configured for translation pattern and the call is diverted to C. For details, see [Use Cases for Calls Going Through Translation Pattern with CEPN Info in Cc Signals, on page 929.](#))

| Actions                                                                                                                                                                   | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**External Call Control on Translation Pattern and CEPM Returns “divert” with Modified Calling and Called Parties with resetCallHistory flag = resetAll**

**Configuration**

Phone A, B are in cluster devices. B matches the translation pattern BXXX which has calling and called party transformation defined to transform A to A1 and B to B1 and External Call Control is also enabled.

Procedure:

Application invokes connect() at A to call B.

**Result**

Dialed number B matches the translation pattern BXXX which has External Call Control enabled. This takes precedence and CUCM requests CEPM to get routing rule for B.

CEPM returns divertTo = “C”, with ModifiedCalling = “MA” and ModifiedCalled = “MB”

C has a userRule configured to DivertTo = “D” with ModifiedCalling = “MMA”, ModifiedCalled = “MMB”, resetCallHistory = “resetAll”

Call will be extended to “D”

| Actions                                                                                                                                                                                                                      | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**External Call Control on Translation Pattern and CEPM Returns <reject> and Service Parameter CTI Use Wildcard Pattern as calledPartyDN Is Set to False**

**Configuration**

Phone A, B are in cluster devices. B matches the translation pattern BXXX which has calling and called party transformation defined to transform A to A1 and B to B1 and External Call Control is also enabled.

Procedure:

Application invokes connect() at A to call B.

**Result**

Dialed number B matches the translation pattern BXXX which has External Call Control enabled. This takes precedence and CUCM requests CEPM to get routing rule for B. The routing rule for B says “Reject”<reject> CEPM returns reject.

Jtapi throws platform exception to the application. A receives ConnFailedEvent (cause = CtiCallRejected), ConnDisconnectedEv (cause = normal), CallInvalidEvent (caue = Normal).

**Transfer and External Call Control with Modified Calling and Called Parties**

**Configuration**

Phone A, B are in cluster devices. B matches the translation pattern BXXX where External Call Control is enabled.

Phone C and D does not match any translation pattern, and have no External Call Control defined.

Procedure:

Application invokes connect() at A to call B. CEPM returns divertTo = C, with ModifiedCalling = "MA" and ModifiedCalled = "MB".

C initiate transfer to D and completes the transfer.

**Result**

Transfer is successfully completed

## Chaperone Use Cases

### Call Is Redirected to a Hunt List of Chaperones and the Chaperone Enables Call Recording and Conferences in the Called Party

#### Configuration

A calls X, X's DN matches the translation pattern where External Call Control is enabled.

CEPM determines this call needs to have a chaperone's supervise. CEPM returns the permit decision with the obligation <divert>, destination HuntPilot B, which is a hunt pilot of chaperones, and a reason string "chaperone".

CUCM redirects the call to the hunt pilot B, and the chaperone C1 answers the call.

After talking to A briefly and discovered that A intended to talk to D, the chaperone C1 starts to establish a conference to D. C1 presses the conference softkey and dials D.

CUCM queries CEPM for the call, with calling user C1 with DN C1, and called user D with DN D.

CEPM returns the response with permit decision with <continue> call routing directive, since the policy server detects that the caller is the chaperone.

CUCM rings D's phone and D answers the call.

C1 presses the conference softkey again, and the conference is established.

The chaperone C1 presses the “record” softkey. This triggers the call recording being setup from C1’s IP phone to the recorder.

As one of the steps to establish recording calls to the recorder, two recording calls setup are first sent to the BIB of C1’s IP phone (INVITE for SIP phone and SCCP only the media message are involved). Note only one recording is shown in the picture.

As another step to establish the recording calls to the recorder, the two calls are then redirected to the recorder.

When the call recording is established successfully, the recording warning tone is playing to the C1’s phone. The recording warning tone is enabled by setting service parameter “Play Recording Notification Tone To Observed Target” to True.

After confirming the call recording is established successfully, the chaperone reads an announcement to both A and D and informs them the call is being recorded.

A and D starts to talk under the supervision of the chaperone.

#### **NOTE**

Chaperones have limited abilities in what they can do on a call. The most obvious example is that they cannot put the call on hold, because they are required to be on the call at all times. To learn more about Chaperone limitations, please see the related sections of the External Call Control FFS.

Call Events:

| Actions                                                                                                                                                                      | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Call info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Call Is Redirected to a Hunt List of Chaperones and the Chaperone Conferences in the Called Party From Application**

**Configuration**

A calls X, X’s DN matches the translation pattern where External Call Control is enabled.

CUCM redirect the call to the hunt pilot B. Call is intercepted by the chaperone and the chaperone C1 answers the call.

After talking to A briefly and discovered that A intended to talk to D, the chaperone C1 starts to establish a conference to D. C1 initiates a consult call to D. A new global call id GC2 is created.

CUCM rings D’s phone and D answers the call.

C1 invokes GC2.conference(GC1) from application.

At this step, request for establishing the conference would fail. Jtapi would throw InvalidStateException with the error code as “Call state not valid”.

In order to establish a conference successfully, application must invoke the conference by passing the CI of the call in which chaperone is the controller as the primary CI. So in this case, if application invokes GC1.conference(GC2), it would be able to establish the conference successfully and if application invokes GC2.conference(GC1), Jtapi would throw an exception.

Also application can use CiscoConnection.isChaperone() API to determine controller is chaperone on which call.

**Scenario Four**

The application controls both A and B; A calls B; B redirects the call to C, which needs both an FAC and a CMC.

| Action                                                                                             | Event                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Hunt List

### Configuration

- HuntList feature is enabled for all use cases, unless otherwise indicated
- HuntList pilot1 : 2000
- HuntList1 LineGroup Member : 3001, 3002, 3003
- HuntList pilot2: 4000
- HuntList2 LineGroup Member : 5001, 5002, 5003

Cisco Hunt Address mentioned in the call models below indicates that CiscoAddress.getType() returns CiscoAddress.HUNT\_PILOT.

**Scenario 1**

| Scenario                                                                                                 | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Note** Note: For this scenario, if the pickup is done from the address of the hunt member that is currently ringing with Auto Pickup disabled, then `getCiscoHuntConnection()` returns the connection to the hunt pilot. If the pickup is done from an address that is in the pickup group but is not the current ringing terminal, then `getCiscoHuntConnection()` returns null. If Auto Pickup is enabled, then `getCiscoHuntConnection()` always returns null after the call is picked up (it does not matter whether the pickup is done from the ringing terminal or from another address in the pickup group). This is true for Pickup, Group Pickup, Other Pickup, and Directed Call Pickup.

**Scenario 15**

Gpickup a ringing hunt list member.

| Scenario                                                                                                                                                                                                          | Result                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Intercom

Configuration: terminal T1 has intercom line A with TargetDN B, label Bob, Unicode label UBob. Terminal T2 has intercom line B. Application provider has both T1 and T2 in control list.

C, Carol, UCarol is in the same intercom group as A, and B.

D, David, UDavid is not in the same intercom group as A, B and C.

| Action                                                                                                          | Result                                                  | Call info |
|-----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|-----------|
| Application opens provider, after provider comes in service, application issues provider.getIntercomAddresses() | JTAPI returns A and B as array of CiscoIntercomAddress. | N.A       |

| Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Result                                                                                                                                                                         | Call info  |

## JTAPI Cisco Unified IP 7931G Phone Interaction

A and C are JTAPI application controllable Addresses. B1 and B2 are Address on Cisco Unified IP 7931G Terminal. Cisco Unified IP 7931G Terminal is configured to do Transfer across Addresses. B1 and B2 has shared Line B1' and B2' respectively configured on JTAPI controllable Terminal.

# Locale Infrastructure Development Scenarios

## Scenario 1—JTAPI Client Machine Has Connectivity to CallManager TFTP Server

- During install, JTAPI client would prompt user to enter TFTP IP address.
- TFTP-IP Address is stored in JTAPI.ini parameter.
- JTAPI Preferences application is run first time, it will take user to language tab to language selection.
- User can select language for running JTAPI Preference application.
- JTAPI Preference application is run second time, it will present UI in the language that user selected before.

## Scenario 2—JTAPI Client Machine Doesn't Have Connectivity to CallManager TFTP Server

- During install JTAPI Client would prompt user to Enter TFTP-IP Address
- TFTP-IP Address is stored in JTAPI.ini parameter.
- JTAPI Preferences application is run first time, it will take user to language tab to language selection but user will have only English language to select.
- JTAPI Preference application is run second time, it will present UI in the English languages.
- TFTP connectivity is restored. Now JTAPI Preferences UI is run, it will take user to language selection

## Scenario 3—JTAPI Client Machine Has Connectivity to CallManager TFTP Server

- During install JTAPI Client would prompt user to Enter TFTP-IP Address
- TFTP-IP Address is stored in JTAPI.ini parameter.
- JTAPI Preferences application is run first time, it will take user to language tab to language selection.
- User can select language for running JTAPI Preference application.
- JTAPI Preference application is run second time, it will present UI in the language that user selected before.
- Now new locale files are available with added support for a new languages.
- User runs JTAPI Preferences application, JTAPI Preferences application would notify user about available.
- Application restart JTAPI Preferences application, user will be support for new language.

# Calling Party Normalization

## Scenario 1—Incoming Call From a PSTN Number (Local) to JTAPI Observed Terminal

| Action                                                                                                                                         | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Call info                                                                                                                                                                                                                                                                                                                                               |

## Call Pickup

The basic test case for the fix was the following:

1. B and C are devices in a call pick up group. A is a device not in it.
2. A calls B.
3. C goes off-hook, and presses the Pickup softkey.
4. C is now on the call with A.

This test was run with variations in which devices were observed, and the full matrix was run. This included:

- Observing A, B, and C
- Observing A and B
- Observing A and C
- Observing B and C
- Observing only A
- Observing only B
- Observing only C

The final test run, observing only C, was the primary concern for this fix, based on customer usage. The feature request was, when only observing C, being able to get information about the original called party (A) on Pickup. All test cases passed and the correct information was displayed for all of them.

For cases 3 and 4, the call information depends on the order of events that JTAPI delivers. If JTAPI delivers the GC1-CallInvalidEvent/CallObservationEndedEv events before the GC2-CiscoCallChangedEv, then the call information, such as calling and called addresses, will be what was seen in GC2. Conversely, if JTAPI delivers the GC1-CallInvalidEvent/CallObservationEndedEv events after the GC2-CiscoCallChangedEv, then the call information, such as calling and called addresses, will be what was seen in GC1.

As an example, if JTAPI delivers the GC1-CallInvalidEvent/CallObservationEndedEv events before the GC2-CiscoCallChangedEv, the Calling Address = C, Called Address = Pickup Number. If JTAPI delivers the GC1-CallInvalidEvent/CallObservationEndedEv events after the GC2-CiscoCallChangedEv, the Calling Address = A, Called Address = B.

These test cases were run with auto-pickup enabled and disabled, and there was much difference in the functionality of the two. Most of the test cases are enumerated below.

The basic call from A to B is the same in all cases, and is only shown in the first case below.

### Scenario One

Observing all devices and auto-pickup enabled.

| Action                                                                                                                                                                                                  | Events | Call info (GCID info)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

The flow of events differs greatly when the auto-pickup option is enabled or disabled. When Auto Call Pickup is disabled and a user presses the Pickup softkey (C), the phone rings. The user has to answer the phone as if it is a normal call. When the phone is ringing, the original call that was created when they went offhook is terminated, they are connected to the existing call, and the old party (B) is removed from the call. There is no CiscoCallChangedEv generated when Auto Call Pickup is disabled, because the call does not change, it is terminated before C joins the new call.

A Group Pickup scenario follows, during which the Group Pickup softkey is used in place of the Pickup softkey. This required actually dialing the number for the pickup group. Group Pickup also is subject to the Auto Call Pickup service parameter. The general flow and call events are identical to the normal Call Pickup scenarios, except with added events for the required dialing of the pickup number.

### **Scenario Three**

Observing all devices with group pickup and auto-pickup enabled.

| Action                                                                               | Call event                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Call ID Info                                                                                                                                                        |

There are only a handful of changes for the above Group Pickup case, and they all directly relate to the extra required step of dialing the pickup number.

**Scenario Four**

Observing all devices with Group Pickup and Auto-Pickup disabled.

The tables above have scenarios during which all of the devices were observed. The devices were run with every possible combination, across all varieties of Pickup and Group Pickup. Parts of the scenarios had the exact same output and others were redundant and are not shown here. For example, device A and B were identical and shown only once.

**Scenario Five**

Only observing device B.

| Action                                                                                                   | Call events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Call IDs/Call info                                                                                                  |

## selectRoute() with Calling Search Space and Feature Priority

The selectRoute() API with calling search space and feature priority as array of int. is shown in the following table.

| Action                                                                                                                                                                                                                                                                                                                                                                       | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Call info                                                   |

## Calling Party IP Address

The following are some examples of call scenarios.

### Basic Call Scenario

- JTAPI application monitors party B
- Party A is an IP phone
- A calls B

- IP Address of A is available to JTAPI application monitoring party B

### Consultation Transfer Scenario

- JTAPI application monitors party C
- Party B is an IP phone
- A talking B
- B initiates a consultation transfer call to C
- IP Address of B is available to JTAPI application monitoring party C.

### Consultation Conference Scenario

- JTAPI application monitors party C
- Party B is an IP phone
- A talking B
- B initiates a consultation conference call to C
- IP Address of B is available to JTAPI application monitoring party C.

### Redirect Scenario

- JTAPI application monitors party B and party C
- Party A is an IP phone
- A calls B
- IP Address of A is available to JTAPI application monitoring party B
- Party A redirects B to party C (
- Calling IP address is not available to JTAPI application monitoring party B (not a supported scenario).
- Calling IP address of B is provided to JTAPI application monitoring party C.

## CiscoJtapiProperties

1. Set Socket Connect Timeout to 5 seconds; Plug out the Ethernet cable for PRIMARY CTI Manager and do a normal provider open. Expected Result: Socket Connect to Primary CTI Manager should fail in not more than 5 secs
2. Set Socket Connect Timeout to 5 seconds; Plug out the Ethernet cable for PRIMARY CTI Manager, set security options to True and do a secured provider open. Expected Result: Socket Connect to Primary CTI Manager should fail in not more than 5 secs (Socket Connect timed-out in ~5 seconds, though it took some additional time initially for verifying security certificates)
3. Set Socket Connect Timeout to 0 seconds; Plug out the Ethernet cable for PRIMARY CTI Manager, set security options to true and do a secured provider open. Expected Result: Socket Connect to Primary CTI

Manager will no longer rely on new Service Parameter (Socket Connect timed-out in ~23 seconds, though it took some additional time initially for verifying security certificates).

## IPv6 Support

### Use Case1 - Basic Call Scenario: Calling Is IPv6 Enabled Phone; Called Is IPv6

| Action                                                                     | Events                                     | Call info/Expected result                                                                                                                                                                                                                                                                                                                                                                                                             |

**Use Case11: Enterprise Parameter “Enable IPv6” is Enabled**

Application does an open provider by providing the list of CTI Manager IPs as

- IPv4 address of CTI Manager1
- IPv6 address of CTI Manager1
- IPv4 address of CTI Manager2
- IPv6 address of CTI Manager2

Now once the JTAPI is able to establish a connection with CTI Manager and later on if CTI Manager1 goes down, in failover attempt application can see delay in connecting as JTAPI will first try to connect with IPv6

address of CTI Manager1 (which is next in the list) even though that IP address is of the same CTI Manager and only once it times out it will try with the IPv4 address of the CTI Manager2 which will succeed (assuming CTI Manager2 is running).

## Provider Open Scenario

1. Service Parameter for Reconnect Attempt is not set (or set to 0), Enterprise parameter “Enable IPv6” is disabled. Application tries to open a provider with IPv4 address. JTAPI will be able to open a connection with CTI manager.
  - CTI Manager is stopped – JTAPI will try reconnecting to CTI manager indefinitely till the CTI Manager is started again and connection is restored.
  - Enterprise parameter “Enable IPv6” is enabled and CTI manager is restarted – JTAPI will be able to reconnect to CTI Manager with the same IPv4 address.
2. Service Parameter for Reconnect Attempt is not set (or set to 0), Enterprise parameter “Enable IPv6” is enabled. Application tries to open a provider with IPv4 address. JTAPI will be able to open a connection with CTI Manager.
  - CTI Manager is stopped – JTAPI will try reconnecting to CTI manager indefinitely till the CTI Manager is started again and connection is restored.
  - Enterprise parameter “Enable IPv6” is disabled and CTI manager is restarted – JTAPI will be able to reconnect to CTI Manager with the same IPv4 address. But, the existing devices registered with IPv6 address will be closed with “CiscoTermRegistrationFailedEv” with a new reason code “IP\_CAPABILITY\_MISMATCH”
3. Service Parameter for Reconnect Attempt is not set (or set to 0), Enterprise parameter “Enable IPv6” is enabled. Application tries to open a provider with IPv6 address. JTAPI will be able to open a connection with CTI Manager.
  - CTI Manager is stopped – JTAPI will try reconnecting to CTI manager indefinitely till the CTI Manager is started again and connection is restored.
  - Enterprise parameter “Enable IPv6” is disabled and CTI manager is restarted – JTAPI will not be able to reconnect to CTI Manager, as it no longer supports IPv6 address but JTAPI will try reconnecting to CTI Manager indefinitely till the time service parameter is again enabled and CTI Service restarted.
4. Service Parameter for Reconnect Attempt is set to some integer value (say 5), Enterprise parameter “Enable IPv6” is disabled. Application tries to open a provider with IPv4 address. JTAPI will be able to open a connection with CTI manager.
  - CTI Manager is stopped – JTAPI will try reconnecting to CTI manager 5 times before closing all the opened devices and provider.
  - Enterprise parameter “Enable IPv6” is enabled and CTI manager is restarted – JTAPI will be able to reconnect to CTI Manager with the same IPv4 address.
5. Service Parameter for Reconnect Attempt is set to some integer value (say 5), Enterprise parameter “Enable IPv6” is enabled. Application tries to open a provider with IPv4 address. JTAPI will be able to open a connection with CTI Manager.

- CTI Manager is stopped – JTAPI will try reconnecting to CTI manager 5 times before closing all the opened devices and provider.
  - Enterprise parameter “Enable IPv6” is disabled and CTI manager is restarted – JTAPI will be able to reconnect to CTI Manager with the same IPv4 address. But, the existing devices registered with IPv6 address will be closed with “CiscoTermRegistrationFailedEv” with a new reason code “IP\_CAPABILITY\_MISMATCH”
6. Service Parameter for Reconnect Attempt is set to some integer value (say 5), Enterprise parameter “Enable IPv6” is enabled. Application tries to open a provider with IPv6 address. JTAPI will be able to open a connection with CTI Manager.
    - CTI Manager is stopped – JTAPI will try reconnecting to CTI manager 5 times before closing all the opened devices and provider.
    - Enterprise parameter “Enable IPv6” is disabled and CTI manager is restarted – JTAPI will not be able to reconnect to CTI Manager, as it no longer supports IPv6 address but JTAPI will try reconnecting to CTI Manager 5 more times (as the same can again be enabled on Cisco Unified Communications Manager) before closing all the devices and provider.
  7. Enterprise parameter “Enable IPv6” is disabled. Application tries to open a provider with IPv6 address. JTAPI will not be able to open a connection with CTI manager. Retry attempts are applicable only if connection gets established once, but since in this scenario even the first attempt is failing so there will be no subsequent reconnect attempts.

Enterprise parameter “Enable IPv6” is enabled. Application does an open provider by providing the list of CTI Manager IPs as

- IPv4 address of CTI Manager1
- IPv6 address of CTI Manager1
- IPv4 address of CTI Manager2
- IPv6 address of CTI Manager2

Now once the JTAPI is able to establish a connection with CTI Manager and later on if CTI Manager1 goes down, in failover attempt application can see delay in connecting as JTAPI will first try to connect with IPv6 address of CTI Manager1 (which is next in the list) even though that IP address is of the same CTI Manager and only onMangerce it times out it will try with the IPv4 address of the CTI Manager2 which will succeed (assuming CTI Manager2 is running).

## Calling Party IP Address Scenarios

1. Ipv6 enabled phone calls a CTI controllable device. Subsequently, the CTI controllable device is monitored by a JTAPI application. JTAPI will generate a CiscoCallCtlConnOfferedEv (non-Route Points) or CiscoRouteEvent (Route Points) notification containing an Ipv6 calling party IP address.
  - getCallingPartyIpAddr() will return NULL
  - getCallingPartyIpAddr\_v6() will return the actual calling Party IPv6 address.
2. Ipv4 enabled phone calls a CTI controllable device. Subsequently, the CTI controllable device is monitored by a JTAPI application. JTAPI will generate a CiscoCallCtlConnOfferedEv (non-Route Points) or CiscoRouteEvent (Route Points) notification containing an Ipv4 calling party IP address (existing behavior)

getCallingPartyIpAddr() will return the actual calling Party IPv4 address.

getCallingPartyIpAddr\_v6() will return NULL.

3. Ipv6 only phone calls a CTI controllable device that is already monitored by a JTAPI application. JTAPI will generate a CiscoCallCtlConnOfferedEv (non-Route Points) or CiscoRouteEvent (Route Points) notification containing an Ipv6 calling party IP address.

getCallingPartyIpAddr() will return NULL

getCallingPartyIpAddr\_v6() will return the actual calling Party IPv6 address

4. Ipv4 enabled phone calls a CTI controllable device that is already monitored by a JTAPI application. JTAPI will generate a CiscoCallCtlConnOfferedEv (non-Route Points) or CiscoRouteEvent (Route Points) notification containing an Ipv4 formatted calling party IP address.

getCallingPartyIpAddr() will return the actual calling Party IPv4 address.

getCallingPartyIpAddr\_v6() will return NULL.

5. Ipv4\_v6(Two Stack) phone calls a CTI controllable device. Subsequently, the CTI controllable device is monitored by a JTAPI application. JTAPI will generate a CiscoCallCtlConnOfferedEv (non-Route Points) or CiscoRouteEvent (Route Points) notification containing an Ipv4 and Ipv6 calling party IP addresses.

getCallingPartyIpAddr() will return the actual calling Party IPv4 address.

getCallingPartyIpAddr\_v6() will return the actual calling Party IPv6 address

6. Ipv4\_v6(Two Stack) phone calls a CTI controllable device that is already monitored by a JTAPI application. JTAPI will generate a CiscoCallCtlConnOfferedEv (non-Route Points) or CiscoRouteEvent (Route Points) notification containing an Ipv4 and Ipv6 calling party IP addresses.

getCallingPartyIpAddr() will return the actual calling Party IPv4 address.

getCallingPartyIpAddr\_v6() will return the actual calling Party IPv6 address

## RTP Addresses

1. An Ipv6 enabled phone calls an Ipv6 JTAPI Observed phone and the call is answered. JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address.
  - CiscoRTPInputStartedEv containing the Ipv6 RTP address of the monitored phone.
2. An Ipv4 enabled phone calls an Ipv4 JTAPI Observed phone and the call is answered. JTAPI will generate(existing behavior):
  - CiscoRTPOutputStartedEv containing the far-end Ipv4 RTP address.
  - CiscoRTPInputStartedEv containing the Ipv4 RTP address of the monitored phone.
3. An Ipv4 enabled phone calls an Ipv6 JTAPI Observed device and the call is answered. JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address which corresponds to the MTP that was automatically inserted by Call Manager to perform Ipv4/Ipv6 conversion.
  - CiscoRTPInputStartedEv containing the Ipv6 RTP address of the monitored phone.

4. An Ipv6 enabled phone calls an Ipv4 JTAPI Observed device and the call is answered. JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv4 RTP address which corresponds to the MTP that was automatically inserted by Call Manager to perform Ipv4/Ipv6 conversion.
  - CiscoRTPInputStartedEv containing the Ipv4 RTP address of the monitored phone.
5. A Dual stack(Ipv4\_v6) phone calls another dual stack(Ipv4\_v6) JTAPI Observed device, preferred media termination is set to IPv6, and the call is answered then JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address of the calling device.
  - CiscoRTPInputStartedEv containing the Ipv6 RTP address of the monitored phone.
6. A Dual stack(Ipv4\_v6) phone calls another dual stack(Ipv4\_v6) JTAPI Observed device, preferred media termination is set to IPv4, and the call is answered then JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv4 RTP address of the calling device.
  - CiscoRTPInputStartedEv containing the Ipv4 RTP address of the monitored phone.
7. A Dual stack(Ipv4\_v6) phone calls an Ipv4 JTAPI Observed device and the call is answered then JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv4 RTP address of the calling device.
  - CiscoRTPInputStartedEv containing the Ipv4 RTP address of the monitored phone.
8. A Dual stack(Ipv4\_v6) phone calls an Ipv6 JTAPI Observed device and the call is answered then JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address of the calling device.
  - CiscoRTPInputStartedEv containing the Ipv6 RTP address of the monitored phone.
9. An IPv4 phone calls a dual stack (Ipv4\_v6) JTAPI Observed device and the call is answered then JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv4 RTP address of the calling device.
  - CiscoRTPInputStartedEv containing the Ipv4 RTP address of the monitored phone.
10. An IPv6 phone calls a dual stack (Ipv4\_v6) JTAPI Observed device and the call is answered then JTAPI will generate:
  - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address of the calling device.
  - CiscoRTPInputStartedEv containing the Ipv6 RTP address of the monitored phone.
11. JTAPI observed IPv6 phone(A) calls JTAPI observed IPv4 phone(B). B answers and consults IPv6 phone(C) for Transfer. C answers and B completes the Transfer, then JTAPI will generate:
  - At A:
    - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address of C.
    - CiscoRTPInputStartedEv containing the Ipv6 RTP address of A.

- At C:
    - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address of A.
    - CiscoRTPInputStartedEv containing the Ipv4 RTP address of C.
12. JTAPI observed IPv4 phone(A) calls JTAPI observed IPv4 phone(B). B answers and consults IPv6 phone(C) for Transfer. C answers and B completes the Transfer, then JTAPI will generate:
- At A:
    - CiscoRTPOutputStartedEv containing the far-end Ipv4 RTP address which corresponds to the MTP that was automatically inserted by Call Manager to perform Ipv4/Ipv6 conversion.
    - CiscoRTPInputStartedEv containing the Ipv4 RTP address of A.
  - At C:
    - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address which corresponds to the MTP that was automatically inserted by Call Manager to perform Ipv4/Ipv6 conversion.
    - CiscoRTPInputStartedEv containing the Ipv6 RTP address of C.
13. JTAPI observed IPv6 phone(A) calls JTAPI observed IPv4 phone(B). B answers and consults IPv6 phone(C) for conference. C answers and B completes the conference. Conference Bridge has an IPv4 address. Then JTAPI will generate:
- At A:
    - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address which corresponds to the MTP that was automatically inserted by Call Manager to perform Ipv4/Ipv6 conversion.
    - CiscoRTPInputStartedEv containing the Ipv6 RTP address of A.
  - At B:
    - CiscoRTPOutputStartedEv containing the far-end Ipv4 RTP address of the Conference Bridge.
    - CiscoRTPInputStartedEv containing the Ipv4 RTP address of B.
  - At C:
    - CiscoRTPOutputStartedEv containing the far-end Ipv6 RTP address which corresponds to the MTP that was automatically inserted by Call Manager to perform Ipv4/Ipv6 conversion.
    - CiscoRTPInputStartedEv containing the Ipv6 RTP address of C.

## CTI Port/Route Point Registration Scenarios

1. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv4\_v6'. Application tries to do a static register of that CTI Port/Route Point to CTIManager with IPv6 address and Application addressing capability as IPv6. The registration will succeed and CTI Port/Route Point will get registered with CTIManager with IPv6 address.

2. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv4\_v6'. Application tries to do a static register of that CTI Port/Route Point to CTIManager with IPv4 address and Application addressing capability as IPv4. The registration will succeed and CTI Port/Route Point will get registered with CTIManager with IPv4 address.
3. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv4\_v6'. Application tries to do a static register of that CTI Port/Route Point to CTIManager with IPv4 and IPv6 addresses and Application addressing capability as IPv4\_v6. The registration will succeed and CTI Port/Route Point will get registered with CTIManager with IPv4 and IPv6 addresses.
4. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv4 only'. Application tries to do a static register of that CTI Port/Route Point to CTIManager with IPv4 address and Application addressing capability as IPv4. The registration will succeed and CTI Port/Route Point will get registered with CTIManager with IPv4 address.
5. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv6 only'. Application tries to do a static register of that CTI Port/Route Point to CTIManager with IPv6 address and Application addressing capability as IPv6. The registration will succeed and CTI Port/Route Point will get registered with CTIManager with IPv6 address.
6. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv4 only'. Application tries a static register of that CTI Port/Route Point by providing an IPv6 address or/and by advertising application addressing capability as IPv6 (or Ipv4\_v6) only then request will fail with a CiscoRegistrationException.
7. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv6 only'. Application tries to dynamically register that CTI Port/Route Point to CTIManager. IP capabilities advertised by the application at the time of registration are IPv4 (or IPv4\_v6) only. Then the request will be denied with a CiscoRegistrationException.
8. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv4 only (or IPv4\_v6 both)'. Application tries to dynamically register that CTI Port/Route Point to CTIManager. IP capabilities advertised by the application at the time of registration are IPv4 only. Then the registration will succeed and CTI Port/Route point will get registered with IPv4 address when the same is provided with SetRTTPParams request.
9. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv6 only (or IPv4\_v6 both)'. Application tries to dynamically register that CTI Port/Route Point to CTIManager. IP capabilities advertised by the application at the time of registration are IPv6 only. Then the registration will succeed and CTI Port/Route point will get registered with IPv6 address when the same is provided with SetRTTPParams request.
10. CTI Port/Route Point has 'IP Addressing Mode' configured as 'IPv4\_v6 both'. Application tries to dynamically register that CTI Port/Route Point to CTIManager. IP capabilities advertised by the application at the time of registration are IPv4\_v6 both. Then the registration will succeed and CTI Port/Route point will get registered with IPv4\_v6 address when the same is provided with SetRTTPParams request.
11. If an application tries to dynamically register a CTI Port/Route Point by advertising its IP capabilities as IPv6, which is already registered to another application with IPv4 address. Then the request will be declined with a CiscoRegistrationException or "CiscoTermRegistrationFailedEv" will be sent with new reason code "IP\_CAPABILITY\_MISMATCH".

## Advance Test Cases

1. Application does a provider Open with IPv4 address to a CTI Manager which has enterprise parameter “Enable IPv6” enabled. Application tries to register a CTI Port/Route point with an IPv6 address whose device IP Addressing Mode is set to “IPv4\_v6” by advertising applications addressing capability as “IPv6 only”. The registration request will succeed.
2. JTAPI observed IPv6 device A calls another JTAPI observed IPv4 device B, call is offered and answered at B. In that case:

CiscoCallCtlConnOfferedEv.getCallingPartyIpAddr() will return NULL

CiscoCallCtlConnOfferedEv.getCallingPartyIpAddr\_v6() will be the actual calling Party IPv6 address

- At B:
  - CiscoRTPInputStartedEv will have B’s IPv4 Address
  - CiscoRTPOutputStartedEv will have IPv4 address of the MTP Resource

Interesting thing to notice here is CiscoRTPOutputStartedEv has an IPv4 address while calling party IP Address is an IPv6 address.

## Direct Transfer Across Lines Use Cases

| Action                                                                                                                                                                                                                                                                  | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Call info/Expected Result                                                                           |

| Do connected Conference Across Lines manually on Phone TB (which supports this feature) to conference GC1 and GC2 | <p>App, gets an PlatformExceptionImpl ("Terminal is restricted",<br/>CiscoJtapiException.CTIERR_DEVICE_RESTRICTED ) when the add observer on TB, B1 and B2</p> <p>GC2: CallCtItermConnHeldEv for TB<br/>GC3: CiscoConsultCallActiveEv<br/>GC3: ConnCreatedEv for B<br/>GC3: ConnConnectedEv for B<br/>GC3: CallCtIConnInitiatedEv for B<br/>GC3: ConnDisconnectedEv for B<br/>GC3: CallCtIConnDisconnectedEv for B<br/>GC3: CallInvalidEvent<br/>GC3: CallObservationEndedEv<br/>GC2: CiscoConferenceStartEv<br/>GC1: CiscoCallChangedEv<br/>GC2: ConnCreatedEv for A<br/>GC2: ConnConnectedEv for A<br/>GC2: CallCtIConnEstablishedEv for A<br/>GC2: TermConnCreatedEv for TA<br/>GC2: TermConnActiveEvent for TA<br/>GC2: CallCtItermConnTalkingEv for TA<br/>GC1: TermConnDroppedEv for TA<br/>GC1: CallCtItermConnDroppedEv for TA<br/>GC1: ConnDisconnectedEv for A<br/>GC1: CallCtIConnDisconnectedEv for A<br/>GC1: ConnDisconnectedEv for B<br/>GC1: CallCtIConnDisconnectedEv for B<br/>GC1: CallInvalidEvent<br/>GC1: CallObservationEndedEv<br/>GC2: CiscoConferenceEndEv</p> | <p>CiscoConferenceStartEv.getControllerAddress() returns<br/>B1CiscoConferenceStartEv.getControllerTerminalName() returns TB</p> |

## Enhanced MWI Use Cases

| Action                                                                                                                                                               | Result                                                                                                                                  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Application calls CiscoAddress.setMessageSummary() to set voice and fax counts on a phone that supports the enhanced message waiting counts.                         | Phone displays updated voice and fax counts provided and also updates the MWI indicator accordingly. A successful response is returned. |
| Application calls CiscoAddress.setMessageSummary() to set voice and fax counts on a phone that does not support the enhanced message waiting counts.                 | Phone only updates the MWI indicator accordingly—no voice and fax counts are displayed on the phone. A successful response is returned  |
| Application calls CiscoAddress.setMessageSummary() to set voice counts, but the “high priority” voice counts provided are bigger than “total” voice counts provided. | The request fails with the following error returned: INVALID_HIGH_PRIORITY_VOICE_COUNTS                                                 |

| Action                                                                                                                                                      | Result                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Application calls <code>CiscoAddress.setMessageSummary()</code> to set fax counts, but the “total” fax counts provided is bigger than maximum size allowed. | The request fails with the following error returned:<br><code>INVALID_TOTAL_FAX_COUNTS</code> |

## Join Across Lines Enhancements

A, C, D, E and F are addresses on different terminals. B1 and B2 are addresses on the same terminal TermB.

A, B1 and C are in a conference call GC1 with B1 as the controller and connected to conference bridge Conference-1. B2, D and E are in conference call GC2 with D as controller and connected to bridge Conference-2.

| Action                                                                                                                  | Events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Park Monitoring Support

Phone B—Cisco Unified IP Phone 7900 Series with SIP/SCCP

Phone A—Future models.

Phone A'—Cisco Unified IP Phone 7900 Series with SIP/SCCP

Park DN—P1, P2

Phone C—Cisco Unified IP Phone 7900 Series with SIP/SCCP

All the default values for the Park Monitoring Reversion timer and Park Monitoring Forward No reversion timers apply.

### Use Case 1: Park Monitoring States

Initial scenario: Application has added Call Observer on A and B. Application has added Address Observer on A. B calls A. A answers.

| Action                                                                                                                                   | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Event/Call info                                                                                                                                                                                                                                                                                     |

## Use Case 10: Filter Enabling or Disabling

Initial Scenario : Initial scenario: Application has added Call Observer on A, B. B calls A. A answers.

| Action                                                                                                                                                                                                                                                                                  | Result                                                                                                                                                                                                                                                                                                                                                              | Event/Call info                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b><br>Initially all filters are disabled in CiscoAddEvFilter <ul style="list-style-type: none"> <li>• Application adds AddressObserver on A.</li> <li>• Application now invokes CiscoConnection.park() on connection on A.</li> <li>• Park reversion timer starts</li> </ul> | <b>Events received at Call Observer on A, B</b><br>GC1 TermConnDroppedEv A<br>GC1 CallCtlTermConnDroppedEv TA<br>GC1 ConnDisconnectedEv A<br>GC1 CallCtlConnDisconnectedEv A<br><br>GC1 ConnCreatedEv P1<br>GC1 ConnInProgressEv P1<br>GC1 CallCtlConnQueuedEv P1<br><br><b>Events received at Address Observer on A</b><br>No event received as filter is disabled |                                                                                                                                                           |
| <b>Step 2</b><br>After step 1, Application invokes setCiscoAddrParkStatusEvFilter(true) but does not invoke CiscoAddress.setFilter(CiscoAddrEvFilter)                                                                                                                                   | <b>Events received at Address Observer on A</b><br>No event received as the address filter is not set.                                                                                                                                                                                                                                                              |                                                                                                                                                           |
| <b>Step 3</b><br>Now the application invokes setFilter(CiscoAddrEvFilter) on CiscoAddress                                                                                                                                                                                               | <b>Events received at Address Observer on A</b><br>CiscoAddrParkStatusEv A                                                                                                                                                                                                                                                                                          | Cause = CAUSE_SNAPSSHOT<br>park state = PARKED<br>sub ID = 1234<br>CiscoCallID = CiscoCallID for GC1<br>park DN = P1<br>parked party = B<br>terminal = TA |

## Additional Use Cases for Park Monitoring

Phone B—Cisco Unified IP Phone 7900 Series with SIP/SCCP

Phone A—Future models.

Phone A’—Cisco Unified IP Phone 7900 Series with SIP/SCCP

Park DN—P1, P2

Phone C—Cisco Unified IP Phone 7900 Series with SIP/SCCP

All the default values for the Park Monitoring Reversion timer and Park Monitoring Forward No reversion timers apply.

1. Initial scenario: Application has added Call Observer on A and B. Application has added Address Observer on A. B calls A. A answers. Filter value has been set to ‘true’ through setCiscoAddrParkStatusEvFilter().

| Action                                                                                                                                                                                    | Result                                                                                                                                                                                                                                                                                                                                                                                                                         | Event/Call info                                                                                                                                                                                                                         |

## Use Cases Related to DPark

Initial set up:

- Application has added call observer on B and A
- User has configured DPark DN **D**

- B is a future model Cisco Unified IP Phone
- A calls B. B answers with GCID GC1

| Call Scenario                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Expected behavior                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

B is connected to DPark DN, but no park operation.</p> |

## Logical Partitioning Feature Use Cases

Redirect from a Logical Partition (LP) Restricted Cluster

Terminal TA is configured with address A and is registered to a cluster which is configured with logical partition restrictions. Terminal TX is registered with address X which is configured to a cluster with no LP configuration.

| Action                                                        | Result                                                                                                                                                         |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>X calls A. A redirects the call to a local PSTN number</p> | <p>PlatformException is thrown to redirect request.<br/>getErrorCode() on the exception returns CiscoJtapiException.<br/>REDIRECT_CALL_PARTITIONING_POLICY</p> |

| Action                                                          | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Call forward:** Call to a address which is forward all to PSTM in GeoLocation with “disallowed” policy

| Action                                                                                                                                                   | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>setForward on A to local PSTN</p> <p>Application is monitoring X.</p> <ul style="list-style-type: none"> <li>X calls A using GC1.connect()</li> </ul> | <p>Connect() API succeeds but the call is dropped due to restrictions on A side.</p> <p><b>Events delivered to call observer of X</b></p> <p>GC1 ConnFailedEv A CAUSE: CiscoCallEv.CAUSE_SERVNOTAVAILUNSPECIFIED</p> <p>GC1 CallCtlConnFailedEv CAUSE:<br/>CiscoCallEv.CAUSE_SERVNOTAVAILUNSPECIFIED</p> <p>GC1: GC1 TermConnDroppedEv X<br/>GC1 CallCtlTermConnDroppedEv TX<br/>GC1 ConnDisconnectedEv X<br/>GC1 CallCtlConnDisconnectedEv X<br/>GC1 ConnDisconnected A<br/>GC1 CallCtlConnDisconnectedEv A<br/>GC1 CallInvalidEv</p> |

**Call Transfer:** Transferring a call from different geo location to PSTN by controller in GeoLocation with “disallowed” policy

| Action                                                                                                                                                       | Result                                                                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <p>X calls A, A consults to PSTN number.</p> <p>Application is monitoring A.</p> <ul style="list-style-type: none"> <li>A completes the transfer.</li> </ul> | <p>Platform exception is thrown to transfer() request.</p> <p>getErrorCode() returns CiscoJtapiException. TRANSFERFAILED</p> |

**Call Conference:** Conferencing a call from different location to PSTN by controller in GeoLocation with “disallowed” policy

| Action                                                                                                 | Result                                                                                                                             |
|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| X calls A, A consults to PSTN number.<br>Application is monitoring A.<br>• A completes the conference. | Platform exception is thrown to conference() request.<br>getErrorCode() returns CiscoJtapiException. CTIERR_FEATURE_NOT_AVAILABLE. |

**Call Park / UnPark:** Parking and un parking a PSTN call.

A and B are in the same cluster but configured in different geo locations with LP restrictions. PSTN is the same geo location as B

| Action                                                                                                                               | Result                                                                                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| PSTN number calls A, A answers and parks the call.<br>Application is monitoring A and B<br>• B un-parks the call using unpark() API. | Call fails:<br>ConnFailedEv A CAUSE: CiscoCallEv.CAUSE_SERVNOTAVAILUNSPECIFIED<br>CallCtlConnFailedEv CAUSE: CiscoCallEv.CAUSE_SERVNOTAVAILUNSPECIFIED |

## Shared Lines

TermA and TermA’ are in the same cluster but configured in different geo locations with LP restrictions. PSTN is the same geo location as TermA.

| Action                                | Result                                                                                                            |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| PSTN number calls A. Only TermA rings | GC1: CallActiveEv<br>GC1: ConnAlertingEv A<br>GC1: TermConnRingingEv TermA<br>GC1: CallCtlTermConnRingingEv TermA |

## Call Park Reversion with Shared Lines in Different Geographic Locations

TermA and TermA’ are in the same cluster but configured in different geo locations with LP restrictions. PSTN is the same geo location as TermA.

| Action                                                                                                              | Result                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| PSTN number calls A, TermA answers and parks the call.<br>After time out call is offered at TermA and not at TermA’ | GC1: CallActiveEv<br>GC1: ConnAlertingEv A<br>GC1: TermConnRingingEv TermA<br>GC1: CallCtlTermConnRingingEv TermA |

## ComponentUpdater Enhancement Use Cases

| Action                                                                                                                     | Result                                       |
|----------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| Application calls ComponentUpdater(null)                                                                                   | Updater.log is created in the same directory |
| Application calls ComponentUpdater("C:\\temp\\")                                                                           | Updater.log is created in c:\\temp           |
| Application calls ComponentUpdater("readonlydirectory")<br>Application does not have write permission to Readonlydirectory | No log is created.                           |

## IPv6 Support

Use case for getIPAddressingMode()

| Action                                                                                                                                                                                                                        | Result                                                                |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <p><b>Step 1</b></p> <p>IP Addressing mode for terminal A in Cisco Unified Communications Manager Admin pages is set as IPv4</p> <p>Application invokes CiscoTerminal.getIPAddressingMode() on terminal A.</p>                | getIPAddressingMode() returns 0                                       |
| <p><b>Step 2</b></p> <p>After step 1, the IP Addressing mode is changed from IPv4 to IPv6. User would be prompted to re set the device.</p> <p>Now application invokes CiscoTerminal.getIPAddressingMode() on terminal A.</p> | getIPAddressingMode() returns 1( provided user had re-set the device) |

## Support for Cisco Unified IP Phone 6900 Series

| Scenario / Description                                                                                                                                                                                                                                | Events to application                                                                                                                                                                                                                                                                                                          |

All of the following use cases use the same basic configuration, unless specifically noted in the use case itself:

Pickup group1: N:P1 ( pickup group number = N, partition = P1)

Pickup group2: M:P1

A, B and C are defined to be in pickup group1

D, E, and F are defined to be in pickup group2

Pickup group2 is subgroup for pickup group1

The following scenarios are basic use cases for the new Call Pickup APIs, and do not require an enumerated event list because of their simplicity. After these, two Call Pickup use cases will be presented so that you can see the new events in place. Interested parties should refer to the Unison JTAPI Interface Specification (EDCS-614242) for the full set of Pickup Use Cases. The Use Cases in that document will not have the new event, but after reading these use cases it should be readily apparent where they belong in the existing use cases.

| Scenario                                                           | Action                                                                                                                                                                                                                                                                                                                                            | Result                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JTAPI Application is observing C                                   | Application opens provider and issues CiscoAddress.getPickupGroupDN() and CiscoAddress.getPickupGroupPartition() at C                                                                                                                                                                                                                             | API returns N and P1 respectively                                                                                                                                                                                                                                                    |
| Cisco UCM service parameter AutoCallPickupEnabled is set to false. | Application opens provider and issues Provider.getCapabilities() and then calls API CiscoProviderCapabilities.canAutoPickup()                                                                                                                                                                                                                     | API returns FALSE                                                                                                                                                                                                                                                                    |
| Cisco UCM service parameter AutoCallPickupEnabled is set to true.  | Application issues Provider.getCapabilities() and then calls API CiscoProviderCapabilities.canAutoPickup()                                                                                                                                                                                                                                        | API returns TRUE                                                                                                                                                                                                                                                                     |
| Cisco UCM service parameter AutoCallPickupEnabled is set to FALSE. | Application opens provider and issues Provider.getCapabilities() and then calls API CiscoProviderCapabilities.canAutoPickup()<br><br>ii). Now administrator sets AutoCallPickupEnabled service parameter to TRUE,<br><br>iii). Application calls API CiscoProviderCapabilities.canAutoPickup()                                                    | i) API returns FALSE<br>ii). CiscoProviderCapabilityChangedEv is delivered<br>iii). API returns TRUE                                                                                                                                                                                 |
| JTAPI Application is observing C.                                  | i) Application opens provider and issues provider.registerPickupAlert(N, P1) to register for pickup alert notification for call pickup group N:P1.<br>ii). A calls B<br>iii). Application opens provider and issues provider.unregisterPickupAlert(N, P1) to register for pickup alert notification for call pickup group N:P1.<br>iv). A calls B | i) Registration successful.<br>ii). After Call Pickup Group notification time, applications gets CiscoProvPickupCallAlertEvent with calling A, Called B, pickup group number : N, pickup group partition: P1<br>iii). Unregistration successful.<br>iv). No Events for pickup alert. |

| Scenario                                                                                                                       | Action                                                                                                                                                                                                                                                                              | Result                                                                                                                                                                                                                                                                    |

As you can see, there are only a handful of changes for this Group Pickup case, and they all directly relate to the extra required step of dialing the Pickup Number. A similar test was run with Auto-Pickup disabled:

**Full-Event Use Case 4 (Observing All Devices): Group Pickup, Auto-Pickup Disabled**

**Invoking Pickup on a Ringing Shared Line (CSCsy30964)**

This is an odd scenario that normal applications will probably not see.

A calls a shared line DN (B), that has SLT1 and SLT2 on it. B is in pickup group N, P1.

B and B' ring, and instead of invoking answer(), the application invokes pickup() on B'.

| Action                                                                                                                                   | Call event                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Call ID/Info                                                                                                                                                                       |

## Media Termination at Route Point

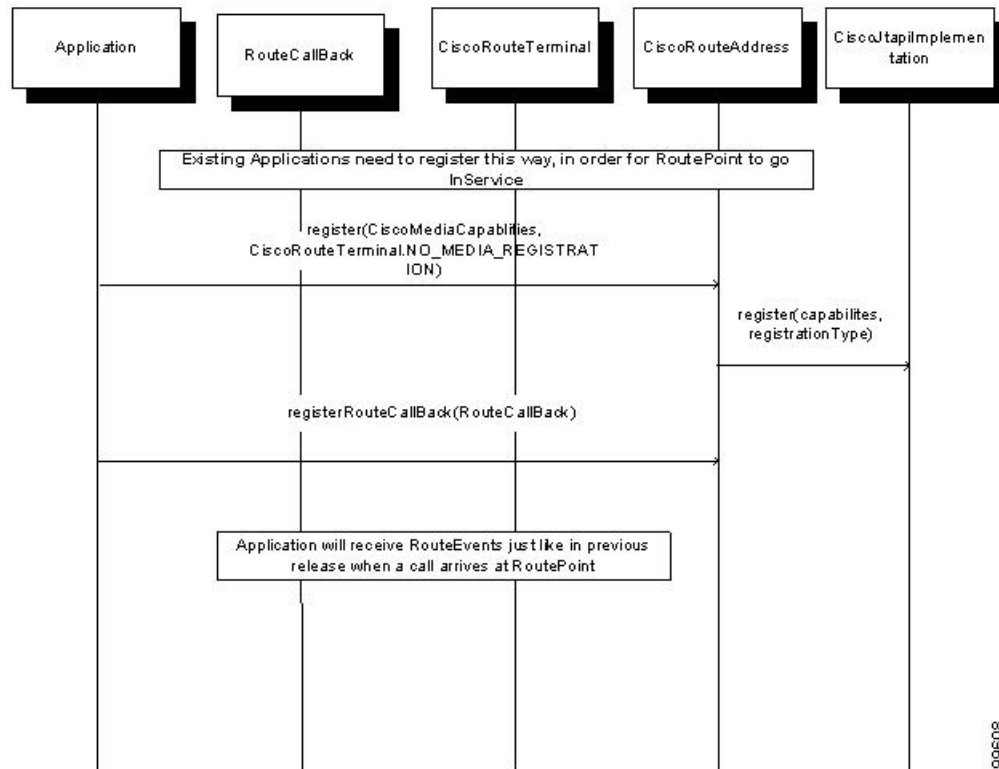

The following diagrams illustrate the message flows for Media Termination at Route Point.

Media Termination at Route Point:  
 In order to set ipAddress and portNo on per call basis for RoutePoint, application needs to register RouteTerminal as specified below and need to add terminalObserver and callObserver.

99607

Media Termination at Route Point:  
Existing applications that need to use RoutePoint for pure routing, needs to register the following way.

99608

## Mobility Interaction Support

Pre-conditions to mobility interaction use cases, unless specified otherwise:

- Provider is in IN\_SERVICE state
- All addresses and terminals are already in service.
- Enable "Route calls to all remote destinations" checkbox for CTIRD1 and CTIRD3.
- CTIRD1 associated to user "Mobility1", dn = 2303
  - Remote destination 1 (Name: "C1\_CTIRD1\_RDD3", Number: "339007")
- CTIRD3 associated to user "Mobility3", dn = 9202
  - Remote destination 1 (Name: "C1\_CTIRD3\_RDD1", Number: "339006")
- RDP1 associated to user "Mobility1", dn = 2303
  - Remote destination 1 (Name: "C1\_CTIRD1\_RDP1", Number: "334007")
- RDP3 associated to user "Mobility3", dn = 9202
  - Remote destination 1 (Name: "C1\_CTIRD3\_RDP1", Number: "334003")
  - Remote destination 2 (Name: "C1\_CTIRD3\_RDD1", Number: "339006")
- Device A (IP Phone - Name: "SEP2401C7824EA3", Line A1 (dn: 9000))

- User1 has in its control list: Device A, CTIRD1 and CTIRD3. All devices and lines are observed.

## Modifying Calling Number

The following scenario illustrates the message flows for Modifying Calling Number.

**Scenario One**

The application controls the device Route Point (RP) and registers RP .

A and B are PNO and appear within the Cisco Unified Communications Manager cluster.

A calls RP.

Call arrives at RP

| Action                                                                                                                                                                                                   | Event          | Fields                                                                                                                                      |

**Scenario Two**

The application is controls A and B.

A calls RP, which selects Route call to B with modified calling number as M.

| Action                                                                                          | Event                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Fields                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
